

# U. S. DEPARTMENT OF COMMERCE BUREAU OF FISHERIES

## REPORT

OF THE

# UNITED STATES COMMISSIONER OF FISHERIES

FOR THE FISCAL YEAR 1938

WITH

# **APPENDIXES**

FRANK T. BELL COMMISSIONER

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1940

#### NOTE

The first section of this volume, entitled "Bureau of Fisheries," constitutes what was known in years prior to 1933 as "Report of the Commissioner of Fisheries." Since then, in the interests of economy, it is a reprint from the "Annual Report of the Secretary of Commerce." The pagination, therefore, is the same as that of the Secretary's Report, rather than beginning with page 1.

## U. S. DEPARTMENT OF COMMERCE BUREAU OF FISHERIES

# HEADQUARTERS STAFF, 1937-38

Commissioner

FRANK T. BELL

Deputy Commissioner.—Charles E. Jackson.
Chief Clerk.—Flossie White.
Chiefs of Divisions:
Fish Culture.—Glen C. Leach.
Inquiry Respecting Food Fishes.—Elmer Higgins.
Fishery Industries.—R. H. Fiedler.
Alaska Service.—Ward T. Bower.
Black Bass and Anglers.—Talbott Denmead.
Director of Aquarium.—Fred G. Orsinger.
Editor.—Harold B. Carr.
Librarian.—Gladys Johnson.

Librarian.—Gladys Johnson. Publications.—Edna N. Sater.

IV

#### BUREAU OF FISHERIES

Based on available statistics for 1936, there was a large increase in the catch of fishery products in the United States and Alaska as compared with the preceding year. Statistics of the catch were collected for both 1935 and 1936 in the Chesapeake, Pacific, and Lake States and in Alaska, and when considering the combined catch of these sections alone, an increase of 22 percent in the volume and 19 percent in the value of the catch is indicated. While these increases are reflected in each of the four geographical sections and in many species, they are especially important in increased catches of pilchard in California and salmon in Alaska.

Based on the most recent surveys, our commercial fisheries gave employment to about 129,000 fishermen, whose catch amounted to 4,840,299,000 pounds, valued at \$92,823,000. The output of canned fishery products in 1936 amounted to 794,707,000 pounds, valued at \$94,564,000, representing an increase of 18 percent in volume and 26 percent in value as compared with 1935; the output of fishery byproducts was valued at \$34,976,000, representing an increase of

17 percent; and the production of frozen fishery byproducts, excluding packaged fishery products, amounted to 106,680,000 pounds, estimated to be valued at \$8,700,000.

The production of fresh and frozen packaged fish, as based on the most recent surveys, amounted to 202,396,000 pounds, valued at \$26,-895,000; and cured fish 116,311,000 pounds, valued at \$15,616,000. is estimated that about 680,000,000 pounds of fresh fishery products (excluding fresh-packaged fish and shellfish), valued at about \$55,-000,000, were marketed during 1936. The total marketed value to domestic primary handlers of all fishery products in 1936 is estimated at about \$236,000,000.

Imports of fishery products for consumption during the calendar year 1936 were valued at \$41,873,000, which is 16 percent more than in 1935, while exports were valued at \$13,214,000, or 8 percent less

than in the previous year.

#### INTERNATIONAL RELATIONS

#### HALIBUT INVESTIGATIONS

The International Fisheries Commission continued the investigation of the life history of the Pacific halibut, and the investigation and regulation of the Pacific halibut fishery, under authority of the treaty of May 9, 1930, and the supplanting treaty of January 29, 1937. The new treaty, which invested the Commission with new powers and responsibilities, did not become effective until August.

Under authority of the 1937 treaty, new regulations were issued August 11, 1937. These differed from the previous ones in several

123251-39-1

respects. They provided for the prohibition of clearance for area 3, when the boats already cleared for fishing were sufficient to catch the limit allowed, and for the setting of a subsequent date of last fishing. They also provided for the retention and sale of a limited proportion of halibut caught incidentally to fishing for other species with set lines in areas closed to halibut fishing. Other changes affected the dates of beginning and termination of the winter closed season.

The Commission recorded the catch from each area, forecast and announced the date of attainment of each area limit and closed the areas accordingly. It issued new regulations on February 26, 1938, changing the regulations of August 1937 by increasing the catch limits in areas 2 and 3 one million pounds each and prohibiting the

use of set nets for the capture of halibut.

The investigations necessary for the fulfillment of the purposes of the treaty included the collection and analysis of the current statistical and biological data, which are necessary for the evaluation of the success of regulation and for continued intelligent control of

the fishery.

Further improvement in the condition of the stocks of halibut was revealed by the investigations. In area 3, which includes the grounds north and west of Cape Spencer, Alaska, the catch per unit of effort was 19 percent greater than in the previous year and 73 percent greater than in 1930, the year when the abundance of halibut reached its lowest ebb. The catch per unit in area 2, which includes the grounds between Cape Spencer and Willapa Harbor, Wash., was slightly greater than in 1936, and 74 percent greater than in 1930.

Extensive market measurements showed that the reduction in the rate of capture of the fish resulting from regulation had produced a further small increase in the size of the fish landed, which, in conjunction with the general increase in abundance, indicated an increase in the spawning stock on the grounds from the previous year. Analysis of the catches of spawn taken in area 2, by means of quantitative net hauls made from a chartered vessel in the winter of 1936–37, showed an increase over the previous three winters. The net hauls were repeated in the winter of 1937–38 and the results are in process of analysis.

Four publications were issued during the year, one report and three circulars. The report, "Theory of the effect of fishing on the stock of halibut," dealt with the theory that explains the past decline of the fishery and its gradual recovery as a result of present regulation. The circulars "Why are there separate areas?", "Halibut tagging experiments," and "The early life history of the halibut," explain in simple form the results of the investigations of the Commission and

their bearing on the regulation of the fishery.

The investigations of the Commission continued to explain the changes taking place in the stocks of halibut on the banks. They prove that the condition of the stocks is still improving, as a result of regulation, and offer new assurance of the ultimate success of the Commission in rebuilding the stocks of halibut to a higher level of productiveness.

#### JAPANESE ACTIVITIES IN THE BRISTOL BAY FISHERIES

Special attention was given during the past year to Japanese fishing operations in Bristol Bay. A number of floating crab canneries and reduction plants have been operated annually in this area by the Japanese since 1930. Their recent activities in the salmon fishery, however, aroused widespread alarm among the Bristol Bay packers and American fishermen. Grave concern was felt lest the interception of the salmon runs bound for Alaskan streams should jeopardize and eventually destroy the long-established Bristol Bay salmon industry.

Following an extensive investigation, this problem was made the subject of diplomatic negotiations between the State Department and the Japanese Government. As a result, assurances were obtained from Japan that it would suspend its official survey of the salmon fishery in Bristol Bay and would issue no licenses to vessels to take salmon in those waters. Continued attention and careful consideration will be given this development to assure the perpetuation of this important American fishery. Funds have been appropriated by Congress for an extensive survey of the Bristol Bay salmon resources, and plans have been made to start the work in the 1938 season.

#### INTERNATIONAL PACIFIC SALMON FISHERIES COMMISSION

The American members of the International Pacific Salmon Fisheries Commission were appointed by President Roosevelt on August 24, 1937, pursuant to ratification on July 28, 1937, of a convention between the United States and Canada for the protection, preservation, and extension of the sockeye salmon fishery of the Fraser River system, tributary of the Puget Sound area of Washington and British Columbia. The American members of the Commission are: Charles E. Jackson, United States Deputy Commissioner of Fisheries; B. M. Brennan, Director of Fisheries of the State of Washington; and E. W. Allen, of Seattle, who is also a member of the International Halibut Commission. The Canadian members who have been appointed are: W. A. Found, Deputy Minister of Fisheries; Tom Reid, Member of Parliament from British Columbia; and A. L. Hager, of Vancouver, B. C.

A. L. Hager was elected chairman and B. M. Brennan secretary at the first meeting of the Commission, held in Vancouver, B. C., on October 28 and 29, 1937. It was agreed that the positions of chairman and secretary of the Commission would alternate between the United States and Canada every 2 years. Dr. W. F. Thompson, Director of Investigations for the International Fisheries Commission, was loaned to the International Pacific Salmon Fisheries Commission on a part-

time basis to initiate the biological investigations.

Studies by the United States Bureau of Fisheries on the condition and trend of the fisheries were discontinued in February 1938, since the work will hereafter be carried on under the International Pacific Salmon Fisheries Commission.

#### CONSERVATION OF WHALES

An international conference held in London on June 8, 1937, resulted in the signing of an agreement with respect to whaling. This agree-

ment supplements the International Whaling Convention of September 24, 1931, and provides greater protection for whales. On June 14, 1938, a further conference was called for the purpose of studying the results of the 1937–38 whaling season, and to consider modification or extension of the 1937 agreement. The conference concluded its business on June 24 by signing an agreement affording still further protection to whales. The Senate has not consented as yet to the ratification of the agreement.

A report on whaling statistics, made by the Bureau of Fisheries in accordance with the requirement of the Convention, was published in the consolidated whaling report of the world, International Whaling

Statistics XI, issued at Oslo, Norway, June 2, 1938.

#### NORTH AMERICAN COUNCIL ON FISHERY INVESTIGATIONS

The twenty-fourth meeting of this Council was held at Montreal, Canada, on September 23, 24, and 25, 1937, with representatives from Canada, Newfoundland, and the United States present. Reports were presented by investigators of the various countries setting forth progress made in the long-time investigations of cod, mackerel, and haddock. New research projects sponsored by the Council and reported on for the first time included a study of the migrations of Atlantic salmon, conducted on a cooperative basis by Newfoundland and Canada, and an extensive program of lobster studies in Canadian waters.

The question of an international treaty for the control of mesh size in nets used by Canadian and United States vessels engaged in the haddock fishery has been under discussion by the Council for several years. Although the voluntary adoption of larger meshed gear by the majority of the New England operators during 1937 has relieved the situation to some extent, the Council continues to recom-

mend coordinated international action.

A discussion of hydrology in relation to fisheries investigations emphasized the fact that this subject may prove to be quite separate from the general problem of oceanic circulation with which the physical oceanographer is principally concerned. The Council directed attention to the fact that routine temperature observations have seldom been available from the fishing banks and recommended that the United States, Canada, and Newfoundland devise means of collecting temperature data on the fishing grounds and also consider the advisability of reporting to the fishing fleet from time to time concerning general temperature trends in important areas.

#### GREAT LAKES FISHERIES CONFERENCE

Progress has been made toward the negotiation of a treaty for the control of the seriously depleted fisheries of the Great Lakes. After nearly 50 years of conferences among the various States attempting to secure uniform regulation by independent State action, a conference was held during February 1938 by members of commissions on interstate cooperation under the auspices of the Council of State Governments. This conference resulted in a definite request directed to the Congress and to the State Department for negotiation of such a treaty. The initial step would provide for the appointment of a

fact-finding commission which doubtless will be instrumental in the drafting of final regulations for the fisheries. At the same meeting progress was made toward the adoption of uniform regulations among the four States bordering on Lake Michigan. Congress subsequently passed legislation which authorized an interstate compact among the Great Lakes States for the preservation of their fisheries.

#### FISHERY ADVISORY COMMITTEE

The Fishery Advisory Committee, composed of leaders in the fishing industry, organized for the purpose of advising the Secretary of Commerce and the Commissioner of Fisheries concerning the development, promotion, and regulation of the fisheries, continued the

study of fishery problems throughout the year.

The lack of current information on market conditions has long been apparent, and the actual establishment of a Market News Service by the Bureau of Fisheries owes much to the recommendations and interest of the committee which foresaw the advantages of this service in the development of a more orderly marketing program for sea foods.

One of the major objectives of the Bureau of Fisheries' investigations is to discover the earliest signs of depletion of a commercial species, since thousands of people are dependent, either directly or indirectly, upon the fishing industry for a livelihood. The problems confronting this group are national and international in scope; many are not easily solved. An outstanding study concerns the difficult problem of the wise exploitation of the pilchard or sardine fishery of the Pacific coast.

The committee has been formulating a long-range program with a view to increasing the year-round consumption of fishery products. A national fish week has been inaugurated and the committee has planned to hold one meeting in a city outside of Washington, D. C., each year. These conferences are resulting in the establishment of closer relations between the industry and Federal agencies concerned, and are affording a better understanding of the problems which the industry is attempting to meet.

#### DOMESTIC RELATIONS

#### COOPERATION WITH OTHER FEDERAL AGENCIES

Some half-dozen Federal agencies are concerned with the management of land and water areas where fisheries conservation may be a problem. Outstanding among these are the National Park Service, Forest Service, Tennessee Valley Authority, Farm Security Administration, Bureau of Reclamation, and the Indian Service. The Bureau has worked with each of these in the solution of their problems.

The Forest Service has constructed during the year more than one-half dozen rearing units which the Bureau operates for the protection of fish to stock park waters. More are under construction and being planned. The existing T. V. A. hatchery at Norris, Tenn., is of insufficient capacity and work has just been started on a large new unit on the Elk River in Alabama. This will be operated by the Bureau and the affiliations with this agency have been most beneficial. The Farm

Security Administration has made preliminary arrangements for transfer to the Bureau of the large hatchery unit at Welaka, Fla. The Bureau has in return supplied fish from its various hatcheries for stocking the waters of recreational projects. Close contact has been maintained in the development of a bass hatchery at Arcadia, R. I., and a program of joint development has been worked out. A hatchery at Hoffman, N. C., was taken over by the Bureau under a similar arrangement.

The Bureau has been the recipient of aid from other Federal agencies. Civilian Conservation Corps enrollees have contributed work at various hatcheries. The Works Progress Administration can, in a number of instances, be credited with improving the physical condition of the Bureau's properties and providing additional facilities

for fish production.

During the past year, the Bureau's technologists gave courses in canning fishery products to State extension service workers at the request of the United States Department of Agriculture. They also rendered considerable assistance to the Bureau of Home Economics of the United States Department of Agriculture in assembling data on the chemical composition and food value of the leading commercial species of fish and shellfish. These data are to be incorporated by the Bureau of Home Economics in a revised publication on the composition of principal American food materials. Chemists of the Food and Drug Administration, United States Department of Agriculture, conferred at length with the Bureau's technologists for the purpose of obtaining information on methods of determining fatty acid in fish meal and the effect of the presence of relatively large amounts of fatty acid in fish meal on its feeding value. The Bureau also cooperated with the Federal Surplus Commodities Corporation in connection with its purchase of surplus fish for relief agencies and with the distribution of this fish to relief clients. The International Fisheries Commission at Seattle, Wash., cooperated in the conduct of several phases of the Bureau's economic and technological work. This included certain technical studies on halibut and halibut liver oil and the collection of economic and statistical data on the North Pacific halibut fisherv.

The Division of Fishery Industries assisted the Rural Electrification Administration in studies of the commercial fisheries in certain areas of Virginia and North Carolina, and assisted the Bureau of Chemistry and Soils of the United States Department of Agriculture in assembling historical data relating to the domestic manufacture of fish

scrap and meal.

The Bureau also has worked with various Federal agencies in obtaining statistical data on our fisheries. In a cooperative arrangement, the Bureau of Agricultural Economics, Department of Agriculture, furnished statistics on the volume of cold-storage holdings of fish and quantities frozen, and the health authorities in Washington, D. C., assisted in obtaining data on the volume of fish handled at the municipal fish wharf and market in this city. Cooperation was accorded the Bureau of the Census in obtaining for that Bureau figures on the volume of the quarterly production and holdings of fish oils in the United States.

#### COOPERATION WITH STATES AND OTHER AGENCIES

An important part of the duties of the field employees of the Division of Fish Culture has been to maintain close cooperation with State fish and game departments for the purpose of coordinating the fish propagation and distribution activities. Similar contacts were maintained with semipublic sportsmen's organizations.

Many State fish and game departments continued to check and review Federal fish applications for their waters. Others exchange eggs and fish with the Bureau or operate hatcheries on a joint basis. In a number of instances the distribution of fish produced at Federal

hatcheries is handled by the State organizations.

New developments along the foregoing lines included the assignment of a skilled Bureau employee to take charge of a new bass hatchery constructed by the West Virginia Conservation Department at Palestine, W. Va. Part of the fish produced will be used for filling Federal applications in that State. When the Missouri Conservation Department was unable to continue operation of the Forest Park Hatchery in St. Louis, the Bureau assumed the obligation and placed an employee in charge.

A tripartite agreement for operations at the brook trout hatchery at York Pond, N. H., was continued in effect with New Hampshire and Vermont. Shad propagation was undertaken in Georgia, the State

cooperating financially.

Sportsmen's organizations have looked to the Bureau for guidance in their stocking problems in an increasing degree. The opening of a trout-rearing and bass-propagating unit at Carpenters Brook, in Onondaga County, N. Y., was the culmination of protracted efforts on the part of the county authorities, the organized sportsmen, and the Bureau. With a Federal employee stationed there, the stocking requirements of this community will be adequately cared for. W. P. A. labor and funds were utilized for construction.

The National Planning Council of Commercial and Game Fish Commissioners, organized at St. Louis, Mo., in 1933, continued its

cooperative work with the States.

The annual council meeting which was held during the week of June 20 at Asheville, N. C., was combined with the International Association of Game Fish and Conservation Commissioners and the American Fishery Society, with representatives from 46 States present.

Among the activities of the National Planning Council of special interest and importance, from the standpoint of State cooperation, has been the benefits to the Bureau resulting from the elimination and

overlapping in fish distribution work.

Subjects of national importance before the organization at the present time are: Fish management, fish culture, shad conservation, pollution problems, Great Lakes fisheries, and the technical problems

of fishery research.

In its technological work, the Bureau has carried on cooperative investigations with several colleges and universities and other State institutions. In these cooperative projects the scientific staffs and other facilities of these agencies were available to the Bureau's staff. Among the institutions cooperating in these investigations are: Wash-

ington State College, Pullman, Wash.; University of Washington, Seattle, Wash.; University of Maryland and Maryland State Agricultural Experiment Station, College Park, Md.; and the Minnesota and Virginia State Departments of Markets.

#### CONSTRUCTION ACTIVITIES

The major construction activities during the year were concentrated upon five new hatcheries. In the Columbia National Forest, near Carson, Wash., a salmon and trout hatchery started during the fiscal year 1937 was completed as far as available appropriations would permit. A hatchery service building, two dwellings, the water system, and several rearing ponds were completed. This new project was necessitated by the partial overflow of the older Little White Salmon hatchery from the waters of the Bonneville Dam pool.

Work was also started on four new pondfish hatcheries located at Lyman, Miss., Marianna, Fla., Cohutta, Ga., and Las Vegas, Nev. These were established in conformity with the act of May 21, 1930, Congress having provided for a resumption of new hatchery development. The Mississippi hatchery was placed on an operating basis during the year, although the proposed pond system was not entirely completed. In Florida about 50 percent of the ponds were completed, and dwellings, service buildings, water supply facilities, etc., were well along toward completion at the end of the year. This hatchery is located in a State park, the site having been donated.

Due to delay in acquiring the site, the Georgia hatchery was less

completely developed both as to ponds and buildings at the close of the year. The appropriation of additional funds permitted the

construction to continue into the fiscal year 1939.

At Las Vegas, Nev., the Bureau took over a hatchery which had been started by the city of Las Vegas. The principal work required was the construction of a dwelling, shop, and garage, and extension of the pond system. The greater part of this had been accomplished by the close of the year. Output of this hatchery will be largely used in restocking Lake Mead.

A site suitable for a bass hatchery in Rhode Island was finally acquired from the Farm Security Administration. A little work was performed in clearing pond sites, but this was suspended for the purpose of developing a project of major construction by utilization of relief labor. W. P. A. aid was enlisted in providing for major improvements at three existing hatcheries. At Edenton, N. C., the work comprised a 100-percent increase in the bass-pond acreage and construction of two experimental rearing ponds for shad. ville, Mass., and White Sulphur Springs, W. Va., a complete rehabilitation of ponds, buildings, and grounds was undertaken. In addition, W. P. A. projects were set up to provide for minor specific repairs and improvements at a number of other hatcheries, notably at San Angelo, Tex., Rochester, Ind., Dexter, N. Mex., and Crawford, Nebr. By the same means, pond construction was continued in the Upper Mississippi Wild Life and Fish Refuge at Genoa, Wis.

A fine stone hatchery building was practically completed at Lamar, Pa., financed by Bureau funds and C. C. C. labor. A series of bass ponds was also started at this point. At York Pond, N. H., a combination of C. C. C. and W. P. A. labor made possible the continua-

tion of the long-range developmental program.

With the installation of hatching troughs and completion of the dwellings by the United States Forest Service, the Walhalla, S. C., hatchery reached its final stage of development.

#### ALASKA FISHERIES SERVICE

#### ADMINISTRATION OF FISHERY LAWS AND REGULATIONS

The excellent condition of the fisheries of Alaska in 1937 reflects the wisdom of conservation policies which have been in effect since 1924. The salmon industry, which is the backbone of Alaska's economic structure, produced the third largest pack on record, and other minor fisheries also continued on a high level of development. Commercial fishing operations in 1937 were closely checked in all areas, and regulations were amended where necessary to assure an adequate escapement of brood fish. The Deputy Commissioner of Fisheries and other officials spent several weeks in Alaska inspecting the fish-

eries and the Pribilof Islands fur-seal industry.

Revised fishery regulations for 1938, issued on February 15, contained only minor changes from the regulations in force in 1937. The restrictions on herring fishing in southeast Alaska were relaxed to some extent, while additional restrictions were placed on herring fishing in the Kodiak and Prince William Sound areas. In a few instances areas open to trap fishing were redefined in order to relieve the drain on certain runs and more nearly equalize the intensity of fishing operations. Clam-fishery regulations were modified to permit a slight increase in the take of razor clams in the Prince William Sound, Copper River, and Bering River areas.

A patrol of the fishing grounds was maintained by 14 Bureau vessels, 1 chartered vessel, and numerous small craft. Twelve statutory employees and 165 temporary stream guards and special workmen, in addition to the crews of the patrol vessels, were engaged in enforcing the fisheries laws and regulations in Alaska. As in previous years, some use was made of airplanes to supplement the vessel patrol and to transport Bureau employees to isolated districts.

No collection of salmon eggs for artificial propagation has been made in Alaska during the past 2 years. The conditions for natural propagation of salmon, however, have been improved by the removal of log jams and other obstructions that hindered the passage of salmon upstream, and by the destruction of predatory enemies of salmon. Funds were made available by the Territorial legislature and by local packers for the payment of a bounty on predatory trout taken in the Bristol Bay and Cook Inlet areas in 1937. In this connection also the Bureau began a scientific study of the migratory habits of Dolly Varden trout in order to provide a rational control program.

Biological studies of salmon and herring were continued and weirs were operated in 12 representative salmon streams to count the escapement of brood fish. The information obtained by weir counts is necessary in determining conservation measures and is also of great value

in connection with the life-history studies of salmon.

#### PRODUCTS OF THE FISHERIES

The total output of Alaska fishery products in 1937 was 452,544,700 pounds, as compared with 523,652,500 pounds in 1936. Notwithstanding this decrease in volume, the value of fisheries products in 1937 was \$51,743,200, an increase of \$1,287,950 over the preceding year. Production of canned salmon in 1937 was the third largest ever recorded, having been exceeded only in 1934 and 1936, and the output of herring products set a new high record for the Territory. There were 30,331

persons engaged in the fishing industry of Alaska in 1937.

Salmon products accounted for 75 percent of the total weight and 90 percent of the total value of Alaska fisheries products in 1937. Ninety-four percent of the salmon production consisted of canned salmon, the pack amounting to 6,669,665 cases, valued at \$44,547,769. This compares favorably in point of value with the record pack of the previous year, which amounted to 8,437,603 cases, valued at \$44,751,633. Red salmon comprised 32 percent and pinks 54 percent of the total pack in 1937, as compared with 30 and 54 percent, respectively, in 1936. One hundred and thirteen canneries were operated, or four less than in the preceding year, and the number of persons employed declined from 25,221 to 24,865 in the same period.

Twenty herring plants were operated in 1937, a decrease of 7 from the preceding year, but the total production of herring meal and oil was the largest in the industry's history. Saltery operations, however, were sharply curtailed, chiefly as a result of unfavorable market conditions. There was a slight decrease in the volume of halibut landings, and the output of cod and shrimp products also declined, but production in other minor fisheries of the Territory, including crabs, clams, and sablefish, showed substantial increases. The two whaling plants which operated in 1937 also reported a slight increase

in production over 1936.

#### ALASKA FUR-SEAL SERVICE

#### GENERAL ACTIVITIES

Sealing and foxing operations were carried on as usual by the native inhabitants of the Pribilof Islands under the direction of the Bureau's staff. Twenty-six skilled employees of the Fouke Fur Co. were detailed to the island for several months to assist in the curing and packing of the skins.

Construction activities on the island were rather limited in 1937. Work on the extension of roads was continued, and minor improvements were made on buildings and equipment. A substation was established on Amehitka Island, one of the western Aleutian group,

to serve as a base for sea otter investigations and patrols.

The byproducts plant on St. Paul Island was operated for the utilization of fur-seal carcasses and produced 29,830 gallons of oil and 165 tons of meal. Small quantities of these products were retained at the islands to be used during the winter for fox feed, but most of the oil was sold in Seattle for the account of the Government, and meal was transferred to the Division of Fish Culture for use as fish food in Federal hatcheries.

The annual supplies for the Pribilof Islands were shipped from Seattle on the U. S. S. Sirius, through the cooperation of the Navy Department. On the return trip to Seattle this vessel carried the season's take of sealskins and 162 tons of seal meal from the by-

products plant.

As the Navy Department's radio facilities at Dutch Harbor, Alaska, have recently been expanded, the maintenance of the St. Paul Island station as a link in the Coast Signal Service is no longer necessary. The St. Paul station was therefore transferred on August 10, 1937, to the Department of Commerce, under a revocable permit, and is being

operated on a reduced scale by the Bureau of Fisheries.

In accordance with the terms of the fur-seal treaty of 1911, delivery of 8,277 fur-seal skins, or 15 percent of the season's take, was made to the Canadian Government. Japan continued to receive its 15 percent share in the take from the proceeds of sale of the remaining skins. The United States received a shipment of 210 Robben Island fur-seal skins, taken by Japan in 1937. This represented the annual 10 percent share due this country under the terms of the fur-seal treaty.

#### SEAL HERD

The total number of animals in the Pribilof Islands fur-seal herd on August 10, 1937, was computed as 1,839,119. This is an increase of 149,376 over the computed number in the preceding year.

#### TAKE OF SEALSKINS

In the calendar year 1937 there were taken on the Pribilof Islands 55,180 fur-seal skins, of which 44,068 were taken from St. Paul Island and 11,112 from St. George Island. This is an increase of 2,734 over the total taken in 1936. Insofar as possible, killings were from the 3-year-old males, a suitable number of this age class having been reserved for breeding stock.

#### SALE OF SEALSKINS

Two public auction sales of fur-seal skins were held at St. Louis, Mo., in the fiscal year 1938. At the sale on September 27, 1937, there were sold 7,000 skins dyed black, 12,580 skins dyed Safari brown, and 147 miscellaneous skins, for a gross total of \$420,640. On May 2, 1938, 7,100 skins dyed black and 12,849 dyed Safari brown brought a gross sum of \$432,622.25.

Sealskins sold at private sales under special authorization by the Secretary of Commerce consisted of 474 dyed black, 398 dyed Safari brown, and 2 raw salted skins, which brought a gross sum of \$21,-102.81. In all, 40,550 fur-seal skins were sold for the account of the Government in the fiscal year 1938, for a total gross sum of

\$874,365.06.

#### FOXES

The blue fox herds maintained on St. Paul and St. George Islands continued to thrive, and the taking of fox pelts provided the natives with employment during the relatively inactive winter months. The herds require very little attention and are a profitable adjunct to the

fur-seal industry. During the 1937-38 season 231 blue and 15 white foxskins were taken on St. Paul Island, and 616 blue and 1 white fox pelt were taken on St. George Island. Sufficient stocks were reserved

on each island for breeding purposes.

One thousand blue and 12 white foxskins, taken on the Pribilof Islands in the 1936-37 season, were sold at public auction in the fiscal year 1938. The blue foxskins brought \$25,934 and the white skins brought \$146, a total gross sum of \$26,080.

#### FUR-SEAL SKINS TAKEN BY NATIVES

Exercising the privilege granted them under the provisions of the North Pacific Sealing Convention of July 7, 1911, the aborigines dwelling on the coast of the North Pacific took a total of 2,832 furseal pelts in 1937. Indians under the jurisdiction of the United States took 161 skins and Canadian Indians took 2,671. All these fur-seal skins were duly authenticated by Government officials of the two countries.

#### FUR-SEAL PATROL

Vessels of the Coast Guard were again assigned by the Secretary of the Treasury to patrol the waters of the North Pacific and Bering Sea for the protection of the fur seals and sea otters in those areas. One vessel of the Bureau of Fisheries also participated in the fur-seal patrol during the northward migration of the herd.

#### PROTECTION OF SEA OTTERS, WALRUSES, AND SEA LIONS

A new edition of the regulations for the protection of walruses and sea lions was issued on July 1, 1937, extending the closed season on these animals for 2 years, although permitting their capture, as heretofore, under certain specified conditions. The killing of sea otters is prohibited at all times.

#### PROPAGATION AND DISTRIBUTION OF FOOD AND GAME FISHES

The hatcheries operated by the Division of Fish Culture released for the stocking of public waters during the fiscal year 1938 a total of 7,822,151,800 fish and eggs. This represents a slight regression, approximately 1.2 percent, from the comparable output of the previous year. The 1938 production has, however, been exceeded only twice during the period in which the Federal Government has operated fish hatcheries. In view of the effects of weather, and other factors beyond control, there is each year an inevitable fluctuation in the output of the hatcheries. Among the factors which may be cited as contributing to the reduction and output was the flooding of the Louisville, Ky., hatchery during the spring of 1937, thereby affecting the 1938 production. In the Madison River, Mont., a large supply of trout eggs was virtually eliminated because of drainage of a hydroelectric reservoir. The cyclical nature of the runs of Pacific salmon also contributed to a reduced egg take for those species. Altogether some 45 different species of fish were handled at the Bureau's hatcheries. The canalization of the upper Mississippi River has curtailed the rescue work in the Upper Mississippi Wildlife Refuge. This was reflected in a reduction of distribution of warm-water pondfish and also in the distribution of a larger-size fish listed as fingerlings. The fingerling output of 118,105,000 was approximately 18,000,000 less than the previous year. The output of game fish as a whole held up most successfully. The demand for game fishes for stocking waters on Federal lands has increased to the extent that many applications from private applicants had to be carried over for subsequent attention.

#### PROPAGATION OF COMMERCIAL SPECIES

Marine species, Atlantic coast.—The output of haddock and pollock, and important species of the New England shore waters, was increased. This increase was balanced by a reduction in the propagation of cod and flatfish. Lobster propagation was prosecuted more vigorously at Boothbay Harbor, Maine, and Gloucester, Mass., with a resultant production of 6,800,000 fry. No mackerel were propagated by the marine stations during 1938. As usual, much of the propagation of marine species was concerned with the fertilization of eggs and their immediate planting on the natural spawning grounds. Over 4½ billion eggs were salvaged by this procedure.

Pacific salmon.—It is especially regretful that there was a notable drop in the propagation of chinook and sockeye, the most valuable species of the Pacific salmons. However, the annual fluctuation in the runs of these fish determines the egg take, which in turn controls the hatchery distribution. In connection with the salmon hatchery

operation, steelhead trout were propagated in large numbers.

Anadromous species, Atlantic coast.—In line with an intensive study of the biology of the shad, and a definite program of rehabilitation of the species, the output of shad fry was materially increased to a total of 26,000,000. Increases were registered at the Fort Belvoir, Va., station and at Edenton, N. C., and scattering numbers were propagated in South Carolina and Georgia, the latter being a new activity conducted in cooperation with these States. Work with the Atlantic salmon was negligible, due to inability to obtain any worth-while quantity of eggs. Yellow perch and white perch were hatched in large numbers in the shad hatcheries, since these species can be handled at little additional cost in connection with the propagation of the more important shad. Effort was again made to propagate striped bass on the Roanoke River in cooperation with the State of North Carolina. Moderately successful results were obtained.

Commercial species, interior waters.—Several hundred million eggs and fry of the catfish, buffalo fish, and carp varieties were distributed, purely as a byproduct of the Bureau's other work in the upper Mississippi area. It would have been possible to increase the output of these had such action been deemed desirable. Owing to uncertainty as to the role of the hatcheries in maintaining the more valuable species of the Great Lakes, there was no increase in intensity of effort to hatch whitefish and lake herring. Seventy-four and one-half million whitefish fry represented a yield somewhat below the previous year. The propagation of pike-perch at the Put in Bay, Ohio, station, in cooperation with the State of Ohio, was resultant of

a reduced output. The feature seriously affecting the work on Lake Ontario is the fact that the most suitable spawning area for white-fish and lake trout is in Canadian waters and no satisfactory arrangements can be made whereby the Bureau can obtain eggs from that source. Similar limitations kept the production of lake trout at a low level.

Game species.—A large increase in the production of black-spotted trout was made possible through increased egg collections at Yellow-stone Park. The greater portion of these fish were distributed in National Park waters. Fewer brook, rainbow, and loch-leven trout were distributed, but many of these were planted at large size, increasing their value for stocking purposes. Efforts to develop a satisfactory and economical trout food under actual operating practices have continued. An important feature of the Bureau's work with game fish is the assignment of trout eggs, particularly of the rainbow trout, to various other fish-cultural agencies. Shipments of rainbow trout eggs and panfish were made to Puerto Rico, while eggs of various species were supplied to Venezuela and Argentina. It is again gratifying to report that the production of bass, a species which merits its great popularity among the sportsmen, exceeded all previous records.

It should be pointed out that practically all new hatchery developments within recent years, exclusive of some minor developments in the Pacific salmon area, have been for the propagation of game species. This is due to the fact that the fishes sought for sport are largely denizens of the lesser fresh waters. They are consequently more vulnerable to the increased fishing pressure of recent years, and, further, suffer from environmental changes, such as pollution,

which mark our national development.

Since hatchery efforts are wasted unless the fish are stocked properly, more intensive consideration was given to the distribution problem. Eight large trucks were acquired, as the nucleus of a fleet, and these were being equipped with special tanks and apparatus at the close of the year. Attempts to economize by inducing private applicants to transport their allotments of fish have been unsatisfactory, due chiefly to the applicants inexperience in handling live fish.

#### RESCUE OPERATIONS

Due to the development of the 9-foot channel in the Upper Mississippi River, the number of fish rescued in that area was below that of 1937. However, there were salvaged a total of 42,202,000 fish, comprising 10 species. Of this number over 41½ million were

returned directly to the main river channels.

The canalization of the Mississippi to the Twin Cities will make the salvage work virtually unnecessary and impossible in the future. In lieu of this the Bureau is constructing large artificial ponds for the propagation of fish in the areas adjacent to the pools created by the new dams. The ponds already constructed and operated have proved very successful. The two in operation at Genoa, Wis., last year produced over 864,000 fingerling black bass alone.

#### FISHERY INDUSTRIES

#### ECONOMIC AND MARKETING INVESTIGATIONS

Surplus fish situation.—A study of the surplus fish situation showed that on March 15, 1938, holdings of frozen, cured, and canned fishery products in the United States amounted to approximately 260,000,000 pounds, which was about 80 to 100 million pounds greater than

normal holdings.

Improved cold-storage statistics.—The Bureau of Fisheries, in cooperation with the Bureau of Agricultural Economics of the Department of Agriculture, has made several revisions in the species classifications of commodities frozen or held in cold storage in this country. These changes, which are reflected in the monthly and annual cold-storage bulletins published by the Bureau, increase the usefulness of these data to interested parties. Recently, separate classifications were adopted for fillets of various species, and new classifications were added for rosefish and swordfish. On July 15, 1938, additional classifications will be included for scallops, shrimp, and sea crawfish

or spiny lobsters.

United States fisheries off foreign coasts.—A study made during the year shows that about 14 percent of the value of the catch of the domestic fisheries is represented by products taken off foreign coasts. Outstanding among such commodities are cod, haddock, and other groundfish taken off the coasts of Newfoundland and Nova Scotia, which were valued at \$4,600,000, and tuna and tunalike fishes taken off the west coasts of Latin America, valued at \$5,900,000. Other domestic fisheries off foreign coasts include those for salmon and halibut off British Columbia; the fishery for red snapper and groupers on Campeche Bank off Mexico; and the whale fishery off Australia. The total value of domestic fisheries off foreign coasts to domestic fisherman amounted to about \$13,000,000.

Commercial fisheries of the world.—On the basis of the most recent available data, the world's annual commercial catch of fishery commodities amounts to about 30,000,000,000 pounds, valued at approximately \$730,000,000. The United States, including Alaska, ranks first in value of the annual yield and is exceeded only by Japan in

volume.

Fishery market news service.—Offices for the daily collection and dissemination of fishery market news were established at New York, N. Y., and Boston, Mass., during the past year. Plans for opening the third office, at Seattle, Wash., were nearing completion at the end of the fiscal year, and other offices, within the facilities of the Bureau, will be opened during next fiscal year. Essentially, this new service, which has proved most popular, constitutes an exchange of market information between the fishermen or producers in fishing areas and the middlemen in terminal markets, with the Bureau of Fisheries acting as the service agency; that is, the agency for collecting and disseminating the news.

Cooperative marketing.—In connection with the administration of Public, No. 464, "An Act authorizing associations of producers of aquatic products," investigations have been continued to determine

the cooperative status of fishery organizations in the United States, and the extent and nature of their activities. Studies pertaining to fishery associations and the financing of fishermen, which were begun in 1936 on the Pacific and Middle and North Atlantic coasts, have been extended to include the South Atlantic and Gulf coasts. It has been found among fishermen and associations visited that there is widespread interest in the possibilities of advancing cooperative marketing activities. This interest has been evidenced further by many requests for the Bureau to give aid of an advisory character concerning operations and management and financing problems. Wherever possible, such assistance has been supplied through correspondence, informative literature, or personal contact.

#### STATISTICAL INVESTIGATIONS

#### FISHERIES OF THE UNITED STATES, CALENDAR YEAR 1936

New England States.—No complete statistical survey of the commercial fisheries of this area was made for 1936. However, the total landings by United States fishing vessels at Boston and Gloucester, Mass., and Portland, Maine, amounted to 414,767,000 pounds, valued at \$11,144,000, an increase of 11 percent in volume and 24 percent in value as compared with the preceding year.

Middle Atlantic States.—No complete survey for the catch of fishery products in these States was made for 1936. A survey made of the shad fishery of the Hudson River for 1936 showed that 476 fishermen took 2,468,000 pounds of shad, valued at \$170,000, an increase of 191 percent in volume and 139 percent in value as compared with 1935.

Chesapeake Bay States.—The commercial fisheries of Maryland and Virginia in 1936 gave employment to 18,283 fishermen. Their catch amounted to 314,095,000 pounds, valued at \$6,488,000, an increase of 18 percent in volume and 17 percent in value as compared with the catch in the provious year.

catch in the previous year.

South Atlantic and Gulf States.—The commercial fisheries of North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas, during 1936, gave employment to 29,006 fishermen. Their catch amounted to 556,993,000 pounds, valued at \$13,542,000, an increase of 24 percent in volume and 36 percent in value as compared with the catch in 1934, when the last previous survey of catch was made.

Pacific Coast States.—During 1936 the commercial fisheries of Washington, Oregon, and California gave employment to 20,620 fishermen, whose catch amounted to 1,925,342,000 pounds, valued at \$24,882,000, an increase of 15 percent in volume and 8 percent in value as compared with 1935. The total catch of halibut by United States and Canadian vessels amounted to 48,054,000 pounds, valued at \$3,603,000, an increase of 5 percent in volume and 11 percent in value as compared with the catch in the preceding year.

Lake States.—In 1936 the commercial fisheries of the United States and Canada, in the Great Lakes and international lake of northern Minnesota (Lakes Ontario, Erie, Huron, Michigan, and Superior, and Namakan and Rainy Lakes, and Lake of the Woods), yielded 124,-408,000 pounds of fishery products. Of the total, United States fishermen took 94,277,000 pounds, valued at \$6,389,000, an increase of 4

percent in volume and 7 percent in value as compared with the catch in the previous year. The Lakes fisheries of the United States gave

employment to 5,623 fishermen in 1936.

Mississippi River and tributaries.—No complete survey of the commercial fisheries of the Mississippi River and tributaries was made for 1936. The catch of Lake Pepin and Lake Keokuk, and the Mississippi River between the two lakes, in 1936, amounted to 8,181,000 pounds, valued at \$378,000, an increase of 22 percent in volume and 34 percent in value as compared with the catch in these waters during 1935.

MANUFACTURED PRODUCTS OF THE UNITED STATES AND ALASKA, CALENDAR YEAR 1936

Fresh and frozen packaged fishery products.—Based on data for 1936, except in the case of packaged shellfish in the New England and Middle Atlantic States, which data are for 1935, the domestic production of fresh and frozen packaged fishery products amounted to 202, 396,000 pounds, valued at \$26,895,000. Important commodities in this group were fresh-shucked oysters, 6,758,000 gallons, valued at \$9,249,000; packaged haddock, 41,187,000 pounds, valued at \$4,266,000; and fresh-cooked crab meat, 7,095,000 pounds, valued at \$2,535,000. Frozen products.—In 1936 the production of frozen fishery products

Amounted to 179,274,000 pounds, estimated to be valued at \$15,000,000. The volume of the production was 20 percent greater than in 1935. The most important products frozen were groundfish, whiting, halibut,

salmon, and mackerel.

Cured products.—The production of cured fishery products, based on data for 1936 in all sections except the New England and Middle Atlantic States, which are for 1935, and the Mississippi River and its tributaries, which are for 1931, amounted to 116,311,000 pounds, valued at \$15,616,000. Important products in this group were smoked salmon, 8,753,000 pounds, valued at \$2,656,000; mild-cured salmon, 11,550,000 pounds, valued at \$2,245,000; and salted boneless cod, 7,951,-000 pounds, valued at \$1,492,000.

Canned fishery products.—Canned fishery products produced in 1936 amounted to 794,707,000 pounds, valued at \$94,564,000, an increase of 18 percent in volume and 26 percent in value, as compared with 1935. Canned salmon was the most important item, accounting for 430,-328,000 pounds, valued at \$50,061,000. Other leading canned fishery products were tuna and tunalike fishes, sardines, shrimp, mackerel,

clam products, and oysters.

Byproducts.—Fishery byproducts produced in 1936 were valued at \$34,976,000, an increase of 17 percent as compared with the previous year. Important products in this group were marine-animal oils and meals and aquatic-shell products.

#### TECHNOLOGICAL INVESTIGATIONS

Preservation of fishery products for food.—During 1937, studies in this field included a further development of electrometric tests for the freshness of fish and their practical or commercial application, studies of rancidity in fish, of lactic acid as a possible index of decomposition in frozen fish, of identification of canned salmon, of changes in the composition of pink salmon, and of the canning of aquatic products. Much interest was shown by the industry during the past year in the

commercial application of the electrometric method for determining the relative freshness of such nonoily fish as haddock developed several years ago by members of the Bureau's technological staff. Consequently, one of the Bureau's technologists was assigned to the laboratories of a large fishery producer, and, as a result, equipment has been designed which is as nearly automatic in operation as is possible and which enables the operator to make determinations upon 10 samples of fish at one time. In this way rapid tests for the freshness of fish purchased can be made without delaying packing activities or other commercial operations. At the present time this test is being used by this firm for the selection of fish which are to be used in fancy packs of quick-frozen products. These products are expected to remain in good condition over a longer period of time than is ordinarily expected where the fish are not selected for their prime condition. One of the changes occurring in fish immediately after death is an increase in the formation of lactic acid, which progresses for some time after death. Bureau technologists have begun a study of this formation of acid as a possible reliable index of the rate of decomposition in frozen

Certain species of salmon undergo considerable apparent physical change during the course of the canning season and the quality and value of the canned product is at present judged somewhat on this The Bureau has undertaken a chemical study of these changes in the hope of determining their true significance. In studying the characteristics of the oil in canned salmon, it was found that those for each species fell between quite definite and more or less separated limits. Regulatory bodies have shown interest in these data as a possible help in identifying the species of salmon after it is canned. During the year the Bureau published a report covering an investigation on the preservation of Pacific oysters. The information obtained during the conduct of this work has been helpful in the beginning of a new oyster-freezing industry in the Pacific Northwest. During the past year experiments have been continued in developing methods for canning fishery products, both in the home and for application on a commercial scale.

Bacteriological studies.—Since the preservation of fish is based on the prevention of spoilage through bacterial action, any device or method which can be found to serve this purpose is vitally important to both the fishing industry and ultimate consumer. Studies on other food products indicate that the use of ultraviolet light rays have been beneficial in lowering the number of spoilage bacteria in milk, meats, bread, etc., thus improving the quality of these foods. Late in 1937 the Bureau's bacteriologists began a study of these ultraviolet light rays in reducing the bacterial count of various fishery products. While this investigation is not yet completed, it has been found that the rays will kill marine bacteria, and we hope to work out a practical and commercially feasible application of this method in the treatment

of fishery products.

Pharmacological studies.—In recent years scientific investigators have recognized the increasing importance of the role of minerals in foods and in feedstuffs for farm animals. Certain minerals have been found to be essential in nutrition, and it has been clearly demonstrated that there is need for a better understanding of other

physiological effects which these minerals may have on the animal organism. For this reason an investigator, trained in pharmacology, was assigned to the Bureau's technological staff several years ago. Studies of the arsenic and copper content of shrimp and oysters, and their physiological or pharmacological effect, have revealed that no deleterious effects are observed as a result of eating these products when these minerals occur in natural organic combination. Similar studies are now being conducted on the natural fluorine content of

fishery products. Preservation of fishery byproducts.—During the year additional data were obtained on the properties and composition of salmon oils. A simple method was developed for the commercial extraction of oil from lean fish livers which do not give up oil by normal treatment. Since the livers yielding the most potent vitamin oils come under this classification, the value of such information can be appreciated. The studies on liver oil extraction also led to practical suggestions on methods for fortifying low-vitamin fish oils. Fish oils and oilbearing fishery products are subject to oxidative deterioration during storage, and the matter of preventing such changes is an important problem of the fishing industry. Further studies have been made on the effectiveness of various materials for inhibiting oxidative change. The oxidation of fat in fish meal causes it to become insoluble in normal fat solvents. This leads to errors in analysis and confusion when sales are based on analytical specifications. Studies are being made to devise an analytical procedure which will eliminate this difficulty. During the year the Bureau published a report on the distribution of vitamins in salmon cannery waste and contributed papers to scientific and trade magazines covering such subjects as the utilization of salmon cannery waste, cereal flours as antioxidants for fishery products, and the determination of fat in fish meal.

Fish cookery.—During the past year, the Bureau continued the development and testing of recipes for the preparation and cookery of fish and shellfish, and carried on practical demonstrations in fish cookery in cooperation with home economics workers and others in various parts of the country. In cooperation with the Federal Surplus Commodities Corporation, some practical demonstrations in fish cookery were conducted for relief workers and others interested in connection with the distribution of fish to persons on relief rolls.

#### BIOLOGICAL FISHERY INVESTIGATIONS

#### INVESTIGATIONS OF COMMERCIAL FISHES

North Atlantic fishery investigations.—Biological studies in the North Atlantic area are concerned chiefly with changes in abundance of the stocks of fish which support New England's extensive and varied fisheries. Specific problems investigated during the year dealt with the causes of the extreme fluctuations in abundance of mackerel and means of predicting such fluctuations; the relation between the existing stocks of haddock and the strain imposed by the present intensive fishery; the economic and biological significance of the extension of otter trawling to include several species in addition to cod and haddock; and the condition of the flounder fisheries in coastal waters from Massachusetts to New York.

In contrast to the record yield for the calendar year 1936, the catch of the New England vessel fisheries during 1937 declined by 6 percent and brought the fishermen a monetary return 12 percent below the value of the previous year's catch. With the exception of cod and flounders, the yield of all important species suffered a decline, and all species except halibut, mackerel, and redfish decreased

sharply in value.

The outstanding event of the year in this area was the decline of the mackerel catch to an unforeseen low which was about one-third of the previous year's level. It is believed this small yield was the result of unusual oceanographic conditions which affected the movements of the mackerel and made them less available to the fishermen, rather than of an actual decline in abundance of corresponding magnitude. This view is supported by the peculiar distribution of the 1937 catch and by the good early season yield in 1938. Nevertheless, these developments emphasize the need for a more accurate mackerel catch forecast. Facilities are lacking for off-shore observations on conditions in the sea which affect migrations, survival of young, and availability of

the mackerel to the fishermen.

Not only did the total catch of the haddock fleet decline in 1937 by 5 percent from 1936 level, but also the daily catches of trawlers showed a drop of about 20 percent in both major producing areas. The scrod haddock (the smallest commercial size) continued to be scarce on the Nova Scotian banks, being only about three-fourths as abundant on Georges as in 1936, and it is believed that the decline will continue. Without further information on the numbers and distribution of haddock of precommercial size, however, no definite prediction can be ventured for the 1938 season. Although facilities for such a survey were completely lacking in 1937, one experimental trawling trip was made in the spring of 1938 through the courtesy of the Woods Hole Oceanographic Institution in permitting the use of the vessel Atlantis for this purpose.

Because of recent sharp changes in the stock of flounders, a survey of the flounder fisheries from New York to Boston was carried to completion during the year, catch data from both sports and recreational fisheries being collected. Highly significant figures on the relative intensity of these two types of fisheries were obtained from the returns of tagging experiments carried out in cooperation with the States of Rhode Island, Connecticut, and New York. An average of about 70 percent of the returns have been made by sportsmen. The same experiments have supplied information on the extent and character of flounder migrations which will aid in devising effective

conservation measures.

Middle and South Atlantic fishery investigations.—Headquarters for the investigation of the coastal fisheries from New York to Florida were transferred during the year from Cambridge, Mass., to College Park, Md., permitting a more centralized attack on the urgent problems of fishery management. In this area total production has not only failed to increase, but has actually declined during the present century, despite economic and technological developments which might have been expected to increase the yield of the fisheries.

which might have been expected to increase the yield of the fisheries.

Studies of the scup, squeteague, sea bass, and flounders have been designed to discover the size and age at which the greatest yield in

pounds can be taken at the lowest cost. These studies indicate that elimination of the present widespread practices of destroying fish below market size and of marketing fish that would be more valuable if allowed to grow to a larger size, offers the greatest promise of improving the condition of these fisheries. Sorting of the catches by pound nets, seines, and otter trawls, whenever possible, is urged.

Causes of the decline in abundance of the Atlantic coast shad, and

Causes of the decline in abundance of the Atlantic coast shad, and measures for restoring the fishery, are being sought in an investigation which was initiated during the year. Because the Hudson River shad catch has staged a spectacular recovery under careful regulation from less than 100,000 pounds in 1917 to nearly 3,000,000 pounds in 1936, this area is being carefully studied to determine what conditions are responsible for the recovery. The fundamental question of the number of spawners necessary to maintain the fishery at a given level of abundance is being attacked by tagging spawning migrants and spent fish, studying scales, and deriving indices of abundance from catch data. The effectiveness of present methods of artificial propagation and the possibility of rearing fry to a greater size before liberation are also being investigated.

Widespread concern over the decline of the striped bass fishery in certain sections of the Atlantic coast during the years immediately preceding 1936 led the Division to undertake an investigation continuing and complementing work done by several of the States. Tagging experiments indicate that the fishery takes a heavy toll of the small sizes before they mature, and it is believed that restriction of the catch of these younger and smaller fish would increase the total yield and augment the number of spawners. Extensive seasonal

migrations were also demonstrated by the tagging.

Shrimp investigations on the South Atlantic and Gulf coasts.— The problem of maintaining the present yield of the shrimp fishery without endangering future supplies was attacked by tagging experiments and the collection of catch records on both coasts and by explora-

tory trawling in the Gulf of Mexico to locate new supplies.

The discovery of large schools of shrimp in the deeper offshore areas of the Gulf, which was made by the vessel *Pelican* during the year, furnished proof of the theory long held by Bureau investigators that the shrimp congregate in deep water after they disappear from inshore fishing grounds in the fall and winter. Since it has been shown that some, at least, of these offshore aggregations are large enough to warrant commercial operations, it is believed that the strain on the immature shrimp inshore may be relieved by offshore fishing with beneficial results to the fishery. By taking more of the large shrimp and fewer of the small, immature stages, fishermen may take the same poundage, but fewer shrimp will be removed from the total available. Commercial fishermen began offshore operations in the early spring months as a result of the surveys by the *Pelican*.

The year's tagging operations resulted in the discovery that at least a portion of the shrimp from as far northward on the Atlantic coast as North Carolina migrate to Florida during the winter. From this fact it is clear that the South Atlantic shrimp fishery should be considered as a unit. The need of better protection of the young shrimp is strongly indicated by the fact that the total catch in this area remains at about the same level despite considerable increases in

the number of boats and amount of gear.

North Pacific and Alaska fishery investigations.—Commercial fishery investigations in northern Pacific waters are concerned with recommending measures for the management and conservation of the salmon runs in the rivers of the Northwestern Coastal States and with maintaining at a productive level the salmon and herring fisheries of

Alaska, over which the Federal Government has jurisdiction.

Rehabilitation of the Columbia River's \$10,000,000 salmon industry is believed to depend in large measure upon the restoration of formerly productive spawning areas which are now unavailable or unsuitable. Approximately 2,500 miles of stream have been surveyed for the purpose of discovering additional spawning grounds that may be restored to use and of locating obstructions to upstream migrants and hazards to seaward migrating fingerlings, such as unscreened irrigation ditches. Data for 2,300 miles of stream which were tabulated during the winter showed a total of 418 dams, of which 288 are temporary and 104 are permanent. Five hundred ninety-five diversions were discovered, 563 of which are used for irrigation. On the basis of surveys covering north central, south central, and southeastern Washington, it is estimated that about 55 percent of the streams surveyed provide suitable spawning areas, but about half of this total is unavailable to fish at low water.

In Alaska, Government regulation of the commercial salmon catch is designed to allow a sufficient number of spawners to escape the fishery to maintain the runs of future years. The effectiveness of such regulations depends upon knowledge of the returns that may be expected from a given spawning escapement. Since past observations have established the fact that the ratio of spawning adults to returns several years later varies considerably, studies of the conditions which govern such fluctuations are of paramount importance. Continuing programs of research are therefore conducted on red salmon at Karluk River and on pink salmon at Little Port Walter in southeastern

Alaska.

Additional evidence was secured during the year indicating that better returns are obtained from red salmon fingerlings that remain in fresh water until their third or fourth year than from those that migrate at an earlier age. It is therefore clear that the discovery of means to improve growth and survival of the young in fresh water will have a definite effect on the size of the runs. Major attention was given during the summers of 1937 and 1938 to an investigation of the effect of predatory Dolly Varden trout in reducing the numbers of young salmon. Little information being available about the migrations, growth rates, and age of this species, a series of marking experiments was carried out to supply such knowledge. Field observations throughout the spawning area showed that the heaviest toll is taken during the spring, at the time the young salmon are entering the lake from the spawning streams.

The long-term study of the pink salmon populations of southeastern Alaska deals chiefly with measuring the success of spawning in the streams each year, and with discovering the effect of various natural conditions on the survival of the young. Because the pink salmon, unlike the red, has a 2-year life cycle, the failure of 1 year's brood has serious effects on the fishery 2 years later. Continuous observations are therefore necessary in order to foresee such poor years and regu-

late the fisheries accordingly. These observations consist in counts of the spawning migrants so that the total egg production may be estimated, followed later in the season by counts of the migrating young. From these figures the fresh water mortality is computed. The total ocean mortality is determined by comparing the number of seaward migrants with the numbers returning 2 years later. Because the survival of eggs has been shown to be affected by the extreme seasonal variations in rainfall and temperature, a meteorological record has been kept during the year at the experimental stream at Little Port Walter to secure accurate data on weather conditions.

Studies of the coho salmon in Puget Sound are concerned with methods of rebuilding the runs which were formerly so important in this area. Studies have been carried on over a period of several years to determine the age at which hatchery reared fry may be released most advantageously. Results show conclusively that long periods of rearing bring much larger returns of adult fish. These studies are being continued and exact costs of rearing and handling are being

computed.

The extensive tagging work of previous years of the Alaska herring was continued, with the result that the migratory habits of practically every commercially important population has been established. The electronic tag detector was again operated successfully for the re-

covery of tagged fish.

Herring in the Cape Ommaney area, from which the bulk of the catch in southeastern Alaska is made, have shown a marked decline in abundance during recent years. This decline is the result of a combination of factors—intensive fishing, migrations, and failure of spawning in 1932, 1933, and 1934. Continued observations on each of these conditions being essential to proper management of the fishery, tagging studies were supplemented by the collection of catch statistics and data on the size and age composition of the catch.

Pacific pilchard investigations.—The phenomenal increase in the landings of the Pacific pilchard fishery to a level three times as great as the total landings of all other kinds of fish in the Pacific Coast States has given rise to public concern over the ability of the resource to provide catches of this size without undergoing depletion. In response to this demand, the Bureau of Fisheries was provided with funds by Congress at the beginning of the fiscal year to investigate

the condition of the resource.

Major attention is being given to the question of determining the intensity of fishing which will provide the maximum yield of fish of greatest commercial value, and, at the same time, leave an adequate spawning stock. Since accurate methods of determining age and estimating abundance are fundamental to the solution of these problems, the early months of the investigation have been devoted chiefly to developing a satisfactory technique of age determination and a method of estimating abundance from catch statistics or by aerial observation of schools. Preservation of an adequate spawning reserve, however, depends on an annual census of egg production which cannot be undertaken without a seagoing vessel.

Great Lakes fisheries investigations.—Because of the severe depletion of the Great Lakes fisheries, now generally recognized, problems of fishery research in this area are concerned chiefly with obtaining

an accurate measure of the abundance of certain species, studying the effect of various types of gear in commercial use, and supplying technical advice to aid State officials in the framing of commercial

fisheries regulations.

An investigation was conducted on Lake Erie to determine the relation between the mesh size of gill nets and both the volume of the catch and the size of individual fish taken. On the basis of these and earlier gill-net studies, the Bureau will recommend a definite mesh size for gill nets used for all species commonly taken in small-meshed nets, and will recommend also an upward revision of present legal size limits for blue pike-perch and saugers in order to provide better protection for spawning females.

Because of the legal provision that net mesh must measure full size at all times, an investigation was carried out to determine the allowance that should be made for shrinkage. The differences among various methods of measuring gill-net meshes are also being determined experimentally. These two investigations will provide for more effective operation of the fundamental conservation measure of

net regulation.

During the year a survey was made to determine the effect of commercial fishing on the game fishes of the Potasannissing Bay area. The findings will be made the basis of recommendations for the

regulation of the fisheries.

Progress was made in compiling and analyzing the extensive collections of data from earlier years. These included a complete analysis of statistics of commercial fisheries of Great Lakes waters under jurisdiction of the State of Michigan, providing records of fluctuations in fishing intensity, yield, and abundance of important commercial species over an 8-year period; a study of the whitefish fisheries of Lake Michigan and Lake Huron; and a comprehensive report on the investigation of Lake Champlain fisheries conducted by the international fact-finding commission in 1930 and 1931.

Life history studies of the yellow perch and Lake Erie whitefish were resumed and studies of the competitive food habits of lake trout and lawyers were completed, the conclusion being reached that both species are predators of the commercially important whitefish family, and that the lawyer through its consumption of invertebrates is also

a food competitor of the whitefish.

Important advances made during the year in State administration of the fisheries were the adoption of the flexible rule method of measuring gill-net meshes by four Great Lakes States and the Province of Ontario, and the passage of a discretionary power act by the Wisconsin Legislature, empowering State conservation officials to enact commercial fisheries regulations by decree.

#### AQUICULTURAL INVESTIGATIONS

Although the yearly output of fresh-water game fishes by State and Federal hatcheries amounts to several billion young fish, it is generally recognized that a commensurate return is not being realized by the several million anglers who seek sport in the Nation's streams. The conclusion is inescapable that some, at least, of the hatchery output is being wasted by being planted under conditions which do not favor survival. Scientific investigations being conducted in the field of

aquiculture are directly concerned with the reduction of this waste by determining at what age and under what conditions fish should be planted to insure maximum returns. Improvement of hatchery practices in feeding and selective breeding and the reduction of loss

through disease are also under investigation.

Fish management practices which have been developed by many years' experimentation are being tested in various national forest areas throughout the country, which serve as excellent natural laboratories for this purpose. In the Pisgah National Forest project, operated in cooperation with the Forest Service, studies were carried out during the year to determine what size of fish and what intensity of stocking produce most satisfactory results. The effects of various stream improvements on the production of fish and food organisms are also the subject of studies which will find widespread application.

In California, experiments of an essentially similar nature were carried out during the summers of 1937 and 1938 in the Convict Creek Experimental Stream. The survival rates of various species, sizes, and numbers of trout were compared as a guide for stocking programs. Among the results obtained was the finding that hatchery fish of 2 inches or more show a surprisingly high survival in wild waters, and that there is a distinct species difference in ability to make adjustments

to new conditions after planting.

The continued operation of test waters in Vermont shows conclusively that stocking alone is not enough to maintain the supply in the waters under observation, for, while the species stocked (brook trout) has shown a consistent decline, the rainbow trout, which is dependent

on natural propagation, has held its own.

Fundamental studies in the science of fish nutrition have been continued at Cortland, N. Y. Two lines of attack were made on the problems presented. The first was concerned with improving current hatchery practices by introducing new foodstuffs that are readily available, and by improving the quality of the mixtures in current use. In this connection a process has been developed for freeing linseed meal of its toxic properties by steaming and pressure cooking, while retaining its important property of binding water or meat juices. Progress has been made toward keeping meats for long periods without loss of nutritive value or physical properties, a development which would decrease the labor and investment in refrigeration equipment and make it possible to purchase meat in quantity at periods of low prices.

Field studies in bass streams are concerned with much the same problems as trout studies in colder waters. Studies in selected waters of natural spawning, survival of the young, their food habits and growth, lead to the tentative conclusion that, in the case of bass, natural propagation is more efficient than artificial, and suggest that management practices should be directed chiefly to the improvement

of natural conditions.

Experimental studies of fish diseases were continued. The value of routine preventive treatments is being tested, and records are being carefully kept of possible mortality from such treatments. No increase in mortality was found among fingerling trout. Controlled infection studies were also conducted with the object of learning more about the method of transmission of certain diseases in hatcheries.

The Disease Service continued to assist in the diagnosis of hatchery disease by examining preserved specimens sent to the Seattle and Washington laboratories. This service is extended to Federal, State, and private fish culturists.

#### POLLUTION INVESTIGATIONS

Every State and every major river system have now been included in the stream-pollution studies conducted from headquarters at Columbia, Mo. Over 150 new localities were investigated during the year and observations were continued at approximately 70 old stations. Data collected from these field and laboratory studies are being applied to the solution of practical fisheries problems. Forty-three major cases of stream pollution were investigated by the staff during the year and reports were prepared for the guidance of officials concerned. In addition, the staff has aided in the solution of some 200 lesser problems. Many manufacturers have cooperated to a gratifying degree in applying the findings of the staff.

Detailed surveys were made of several artificial impoundments of water, and practical applications of these studies have been made in connection with the stocking programs of various Western streams on which impoundments have been built or are contemplated.

#### SHELLFISH INVESTIGATIONS

Oysters continue to hold second place in value among all fishery products. The industry is troubled, however, by the increasing depletion of the natural beds, the destruction of valuable bottoms by pollu-

tion, and the losses caused by natural enemies.

In the New England area the principal problems are those of obtaining an adequate set of larval oysters and of protecting the beds from Information on the expected time of spawning and setting was distributed at weekly intervals during both the 1937 and 1938 seasons through the cooperation of the Connecticut Shellfisheries Com-This information was based on systematic observations of water temperatures and the condition of oysters at selected points in Long Island Sound. It is hoped to extend this service to other areas in the near future.

The destruction of most of the early season set of oysters in 1937 by starfish demonstrates the importance of studies for their control which were carried on intensively from the Milford, Conn., laboratory during the winter and spring. A chemical method of control was applied under both field and laboratory conditions and its effectiveness in destroying starfish was established. Careful tests have revealed no

injury to oysters.

Ecological observations were made by the staff during the year at other points on Long Island Sound and in the inshore waters of Virginia, North Carolina, Alabama, and Florida. These observations have guided State authorities and private oyster growers in transplanting seed and planting material for the collection of set. were also prepared for the rehabilitation of several depleted areas.

Studies under way from the new marine laboratory at Pensacola, Fla., include surveys of the condition of local oyster beds and the collection of hydrographic data and plankton samples at selected

points.

A preliminary report was published during the year setting forth the causes of the decline in oyster production which has been strikingly evident in the York River, Va. Field and laboratory studies have demonstrated that the effluent from a local pulp mill is toxic to oysters and that its discharge into the York River is primarily responsible for unfavorable conditions in this area. Further chemical studies of the effluent are being continued to determine which of its constituents are most toxic.

#### LAW ENFORCEMENT DIVISION

This Division is concerned with the enforcement of the act of 1931, regulating interstate commerce in black bass, and work incident to the Whaling Treaty Act of May 1, 1936, to give effect to whaling treaties. This Division also conducts an anglers' service, and issues

permits for the taking of bait fish in the District of Columbia.

The black bass law.—There has been no change in the manner of administering the Federal black bass law since last year. In cooperation with the States, approximately 100 investigations have been made of alleged illegal shipments of black bass, many of which have resulted in obtaining evidence on which prosecutions can be based in either Federal or State courts. In many cases seizures of black bass were made, and objectives obtained without recourse to court procedure.

In connection with the administration of the black bass law, the Division assists the States in the improvement of their angling laws, and in bettering black bass conditions in other ways. The Bureau has received excellent cooperation from the States in this work. The usual publications on fish laws, angling, etc., have been renewed and

distributed, to supply an increasing demand.

Whaling.—A total of 25 licenses to take and process whales were issued by the Secretary of Commerce to 2 floating factory ships, 1 shore station, and 22 catcher boats which are operated from the factory ships and shore stations. The total revenue received from these licenses was \$7,000, which was turned over to the United States Treasury. One scientific permit was issued to import a Right Whale for scientific purposes.

The enforcement of the whaling laws is primarily the duty of the Coast Guard and the Bureau of Customs, with which the Bureau of

Fisheries cooperates.

The Department is charged in the Whaling Treaty Act with the collection of statistical and biological whaling data in addition to the issuance of licenses. The Division has prepared two statistical reports covering the number of whales taken, species, sex, size, etc., which have been forwarded to the Association of Whaling Companies, Sandefjord, Norway, as required by treaty, and has completed biological examinations of a large number of samples of whale stomach contents from whales captured by United States whalers.

Angling.—A large part of the time of the Division is taken up in answering questions relative to how, when, and where to fish. Complete information on fishing tackle, fishing laws, etc., has been assem-

bled in the Division for the use of anglers.

#### VESSELS

Fifteen vessels of the Alaska service cruised about 115,000 nautical miles in the fiscal year 1938, as compared with 131,000 miles in the preceding year. The *Penquin* covered approximately 30,000 miles, the *Brant* about 12,000 miles, and the *Crane*, *Scoter*, and *Teal* each about 10,000 miles.

The *Penguin* made five round trips between Seattle and the Pribilof Islands, transporting personnel and emergency supplies. Interisland service was performed, and native workmen from the Alaska Peninsula were transported to the Pribilof Islands to assist with the sealing activities. Two trips were made to the western Aleutians, one in July and one in September, in connection with the sea-otter patrol.

The Auklet, Kittiwake, Merganser, Murre, and Widgeon were engaged in fishery protective work in southeast Alaska during the 1937 season. The Blue Wing operated on Prince William Sound, the Eider in the Kodiak area, the Ibis at Chignik, the Red Wing in the Alaska Peninsula area, and the Coot on the Yukon River. The Crane transported personnel and supplies between Seattle and Bristol Bay in May and August and patrolled the Alaska Peninsula area during the intervening period.

The Scoter was used on Bristol Bay during the fishing season there and then participated in the patrol of the Alaska Peninsula area for a short time. From about the middle of August to the middle of September it was engaged in the patrol and stream-survey work in the Kodiak area; similar duty was performed later in the vicinity of Craig in southeast Alaska. The Teal was engaged in herring tagging operations in southeast Alaska in the spring, after which it carried on the patrol in Cook Inlet from May to August and on Prince William Sound for a few weeks in September.

The *Brant* was used primarily for general supervisory work, chiefly in southeast Alaska, although one cruise was made as far westward as Dutch Harbor in July.

In the spring of 1938 the Scoter assisted with the fur-seal patrol in

the vicinity of Neah Bay, Wash.

The *Pelican*, which was reconditioned during the previous year for use in shrimp investigations in the South Atlantic and Gulf areas, was engaged in exploratory trawling in offshore waters in the Gulf of Mexico during the greater part of the winter and spring.

#### APPROPRIATIONS

Appropriations for the Bureau for the fiscal year aggregated \$1,967,000, as follows:

Salaries, Commissioner's office	\$150, 400
Propagation of food fishes (including \$260,000 for construction)	929, 000
Maintenance of vessels	168,000
Inquiry respecting food fishes	262, 000
Fishery industries	73, 600
Fishery market news service	75,000
Alaska fisheries service	274,000
Enforcement of black bass law	13, 500
Mississippi Wild Life and Fish Refuge	17, 900
Whaling Treaty Act	3, 600
_	

1,967,000

APPENDIX I TO REPORT OF COMMISSIONER OF FISHERIES FOR THE FISCAL YEAR 1938

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1938

### ADMINISTRATIVE REPORT SERIES

Since the beginning of the Administrative Report Series, considerable confusion has arisen concerning the system of numbering the separates composing it. Inasmuch as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No. —." Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 25 were, they are numbered for filing purposes as follows:

- No. 1. Report, Commissioner of Fisheries, 1931.
- No. 2. Alaska Fishery and Fur-Seal Industries, 1930.
- No. 3. Fishery Industries of the United States, 1930.
- No. 4. Progress in Biological Inquiries, 1930.
- No. 5. Propagation and Distribution of Food Fishes, 1931.
- No. 6. Report, Commissioner of Fisheries, 1932.
- No. 7. Alaska Fishery and Fur-Seal Industries, 1931.
- No. 8. Fishery Industries of the United States, 1931.
- No. 9. Progress in Biological Inquiries, 1931.
- No. 10. Propagation and Distribution of Food Fishes, 1932.
- No. 11. Alaska Fishery and Fur-Seal Industries, 1932.
- No. 12. Progress in Biological Inquiries, 1932.
- No. 13. Fishery Industries of the United States, 1932.
- No. 14. Propagation and Distribution of Food Fishes, 1933.
- No. 15. Fishery Industries of the United States, 1933.
- No. 16. Alaska Fishery and Fur-Seal Inquiries, 1933.
- No. 17. Progress in Biological Inquiries, 1933. No. 18. Propagation and Distribution of Food Fishes, 1934.
- No. 19. Alaska Fishery and Fur-Seal Industries, 1934.
- No. 20. Fishery Industries of the United States, 1934.
- No. 21. Progress in Biological Inquiries, 1934.
- No. 22. Propagation and Distribution of Food Fishes, 1935.
- No. 23. Alaska Fishery and Fur-Seal Industries, 1935.
- No. 24. Fishery Industries of the United States, 1935.
- No. 25. Propagation and Distribution of Food Fishes, 1936.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the Report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

# INTRODUCTION

To an ever-increasing degree, efforts in the field of fishery science are bringing the resources of the waters under a measure of human control. Particularly is this true of the important shellfish supplies

<sup>&</sup>lt;sup>1</sup> Administrative Report No. 30, Appendix I to Report of the U.S. Commissioner of Fisheries for 1938 Approved for publication June 4, 1938.

of the Atlantic, Gulf, and Pacific coasts and of the stocks of game and commercial fishes in the interior waters. Principles of fish management developed by scientific research have been applied with conspicuous success to these fisheries. The application of similar management practices to the great marine fisheries is relatively a virgin field, but

one in which encouraging progress is being made.

As a basis for effective fish husbandry, direct and continuing observations of the fisheries themselves are essential. In addition, fundamental problems of fishery conservation are often solved only with the aid of highly technical laboratory research. Both types of studies are necessarily carried on over long periods of time, and progress reported in any particular year must be interpreted in relation to the whole program of investigations of which it forms a part. Nevertheless outstanding trends and developments in the commercial fisheries during the year 1937, as well as important achievements in the biological investigations conducted by the Division of Scientific Inquiry.

may well be summarized at this time.

Commercial Fisheries.—In the North Atlantic area notable developments occurred in both the mackerel and haddock fisheries. spectacular decline of the mackerel catch to a level which was only about one-third of the previous year's yield was an event of economic and biological consequence, resulting in a sharp increase in price per pound, but in a greatly reduced total return. This decline, of unforeseen magnitude, is believed to be the result of oceanographic conditions at present not understood, which prevented the mackerel from congregating in the usual fishing areas. The year continued the downward trend in haddock landings begun in 1931. Of even greater significance is the fact that it was the first year of simultaneous decline in abundance (as measured in terms of catch per trawler per day) on the Georges and Nova Scotian banks. Declining abundance on Georges Bank drove the greater part of the otter trawl fleet to the distant Nova Scotian banks in 1934, giving the former area an opportunity for moderate recovery. By 1936, however, the catch per day on the Nova Scotian banks began to decline and a return to Georges Bank followed, again increasing the strain on the inshore banks. a result of these shifts, both major haddock areas are now in a state of declining abundance. The developments in these two fisheries emphasize the need for continuation and extension of the biological studies that have been prosecuted by the Division in this area. It is the purpose of these studies to provide knowledge of the limits of safe exploitation by the haddock fishery and to establish a sound basis for prediction of fluctuations in mackerel abundance.

A program of studies designed to direct the rehabilitation of the seriously depleted shad fishery was initiated during the year in the Middle and South Atlantic area. Headquarters for the fishery investigations of this entire section have been transferred from Massachusetts to a more centralized location at College Park, Md., and a field laboratory has been established at Charleston, S. C. A survey of Long Island fisheries by the Bureau staff in cooperation with the New York Conservation Department has been launched to provide information on the relative intensity of the commercial and the growing sports fisheries of this region. A flounder tagging program carried out by the Bureau in cooperation with the State of Rhode Island has already demonstrated that the catch by sportsmen in many cases

forms a significant proportion of the total poundage taken. Continued studies of scup, squeteague, and other fishes which migrate widely along the Atlantic coast, as well as of such anadromous species as shad and striped bass, are expected to provide basic knowledge for the application of fishery management practices which are critically

needed in this area.

In the shrimp fishery of the South Atlantic coast the picture is one of continued increase in number of boats and amount of gear fished and of a catch which fails to increase in spite of augmented fishing effort. Fishing operations are consequently growing less profitable and the need of better protection for the young shrimp is clearly indicated. The tagging program, continued through 1937, gave additional information on the coastwise movements of shrimp and demonstrated that protection of the supply is an interstate problem. Investigations on both South Atlantic and Gulf coasts were pursued jointly with the conservation departments of several southern states for the purpose of devising a system of rational management

for the fishery.

regulation be found necessary.

To provide a continuous fund of information for their proper regulation, studies of the salmon fisheries of Alaska were continued without interruption or material change. In the Karluk area, where effort is being concentrated on the causes of fresh water mortality among young red salmon, marked progress was made in studies of predatory species. Further light on the factors which affect the returns from escapements of pink salmon was gained, and tagging experiments on sockeye, coho, and chinook salmon were continued in the Puget Sound area and on the Columbia River. Progress may also be reported on the investigation of the entire Columbia River Basin to determine what protective and restorative measures are necessary for the protection of the salmon runs of that river. Approximately 2,300 miles of stream have now been surveyed in the Columbia watershed for the purpose of discovering additional spawning grounds that may be restored for use by salmon and of locating obstructions to migrating fish and hazards to downstream migrants in the form of unscreened irrigation ditches.

During the latter part of the year headquarters were established in California for the investigation of the pilchard fishery. Greatly increased exploitation of the Pacific sardine or pilchard within recent years has given rise to fears for the safety of the resource. The investigation is planned to determine whether overfishing exists and to prescribe proper measures for regulation of the fishery, should

Important advances in State administration of the fisheries have been made during the year in the Great Lakes area with the adoption of the flexible rule method of measuring gill net meshes by Wisconsin, Illinois, Michigan, and Ohio, and the passage of a discretionary power act by the Wisconsin legislature, giving wider legislative powers to State conservation officials. Continuing its cooperation with State officials and the fishing industry, the Great Lakes staff has acted in a fact-finding and advisory capacity in several important conservation problems during the year. Life history studies of important commercial species have been continued and statistical analyses of commercial fishing records have provided additional evidence of the severe depletion existing in the Great Lakes fisheries.

Shellfisheries.—Oyster investigations during the year added to the physiological and ecological knowledge on which successful oyster culture is based. In the New England section there was inaugurated the important service of predicting the time and relative intensity of spawning and setting, thus enabling growers to plant their shells at the proper time to obtain the maximum set of larval oysters. Studies on the starfish demonstrated clearly that the control of this destructive enemy of the oyster is an interstate problem and that more effective and better coordinated measures must be taken for its eradication. Experiments looking toward chemical control of starfish have progressed to such a point that their practical application during 1938 seems assured. Additional evidence has been secured of the detrimental effect of pulp-mill effluent on shellfish. the precise nature and physiological effect of the effluent will be of great assistance in any efforts that may be made to remedy this pollution hazard. Ecological surveys made by the staff in Long Island Sound, Virginia, North Carolina, Alabama, and Florida have been used by State conservation authorities for the protection and improvement of shellfish resources of the coast. During the year a new laboratory was established at Pensacola, Fla., to serve as headquarters for oyster investigations of the Gulf area.

Fresh water fisheries.-In recognition of the critical need for a broader basis of scientific fact to direct the rapidly expanding fish cultural operations throughout the country, investigations of the aquicultural staff have been directed in particular toward the development of new and more effective methods, both in the rearing and stocking of fish. The continued operation of test streams in Vermont has demonstrated the value of this procedure as a yardstick for measuring the success of stocking in trout waters. The Pisgah National Forest in which an experimental project has now been under way for more than a year provides an excellent natural laboratory for the application and testing of fish management practices. Here studies are under way to determine the size of fish and the intensity of stocking which produce most satisfactory results and to test the effect of various types of stream improvement on the production of fish and food organisms. Through the operation of experimental streams in California, data are being collected on the survival rates of hatchery trout planted at various ages and under varying predator conditions. The accumulation of such information over a period of

years will serve as a definite guide for stocking programs.

In the fundamental nutrition studies which have been continued at Cortland, N. Y., current hatchery feeding practices are being improved through the testing of a great variety of products. Through biochemical and physiological studies, an attack has been made on the important problem of so adjusting the growth rate of hatchery fish that the most desirable physical development will be produced.

Because fish management practices as applied to bass have received little attention from fish culturists in general, fundamental problems in this field remain unsolved. Determination of the effectiveness of natural propagation, which in the case of bass may prove to be more efficient than artificial propagation, is obviously a first consideration. Observations on the time of spawning, the production of fry, and the food and growth of the young bass have therefore been conducted

during the year in selected waters. Continuation of these studies gives promise of yielding results of great practical importance by indicating whether the efforts of fish culturists may more profitably be spent on artificial propagation or on the improvement of natural conditions in bass waters.

At the Quilcene, Wash., hatchery, both preventive and therapeutic measures for combating common hatchery diseases were investigated under controlled conditions. The superiority of this experimental approach to the problem of hatchery disease has already been clearly demonstrated during the comparatively short time the laboratory has

been in operation.

Every State and every major river system have now been included in the stream pollution studies conducted from headquarters at Columbia, Mo. Data so gathered have been applied to the solution of numerous fisheries problems, and applications of these findings are being made by manufacturers for the correction of pollution hazards with increasing and encouraging frequency. Physiological experiments to determine the cumulative effect of substances naturally present in many waters in minute quantities have yielded results of great significance. In cooperation with the National Research Council, investigations of the fisheries problems in several of the larger impoundments of water in the western part of the country have been initiated. Results of these studies, as yet incomplete, are already finding practical application in connection with stocking programs.

# COOPERATION

As in previous years, the Bureau again gratefully acknowledges extensive cooperation in the conduct of biological investigations of the fisheries which, during the past year, has extended and rounded out materially the program of work. This cooperation includes active participation in research projects by the personnel of the Bureau of Fisheries and other agencies, the furnishing of laboratory and office quarters, equipment, boats, personnel, and other facilities and services, and, in some cases, the donation of funds to joint projects. Such cooperation has been affor led by universities, research institutions, agencies of the State governments, such as fish and game commissions and surveys, and various Federal agencies concerned with the management of natural resources with collateral interests in fisheries.

Several of the sections of the Division of Scientific Inquiry are afforded headquarters for their regional activities by the universities where laboratory and library facilities are unexcelled. Cooperation from the States has consisted generally in the furnishing of office and laboratory headquarters, the provision of boats and assisting personnel, and in some cases the active participation in investigative programs with a joint staff of Federal and State employees. In one instance a brief investigation was undertaken entirely on funds provided by a commercial fishery organization.

Cooperation with Federal agencies has shown continued improvement during the past year. A cooperative program with the Forest Service is continuing upon a mutually satisfactory basis and similar cooperation has been effected with the Tennessee Valley Authority. The Reclamation Service with the assistance of the Bureau is undertaking increased activities in protecting fisheries from irrigation projects. The Federal Power Commission is supporting the Bureau's efforts to provide suitable fish protection on all projects constructed under license from that agency in accordance with law. The Bureau has been able also to extend its cooperation with the Indian Service in the development and protection of the fishery resources on reser-Through the work of the National Resources Committee and the Council of State Governments, both of which agencies have called upon the Bureau for assistance, additional attention is being given to the development of coordinated programs of fishery conservation throughout the country demonstrating again the opportunities for effectively integrating all of the activities of government at various levels in this field.

Specific acknowledgment of cooperation afforded by the various agencies is generally included in each of the succeeding sections of

this report.

# PUBLICATIONS

Owing to the curtailment of funds for printing, the number of publications resulting from investigations of the staff has been reduced. The list of papers published by the Bureau during 1937 follows:

GALTSOFF, PAUL S., H. F. PRYTHERCH and J. B. ENGLE.

Natural history and methods of controlling the common oyster drills (Urosalpinx cinerca Say and Eupleura caudata Say). Fishery Circular No. 25, 24 pp., 13 figs.

HIGGINS, ELMER.

Progress in Biological Inquiries, 1936. Administrative Report No. 29,

HILDERBRAND, SAMUEL F., and LOUELLA E. CABLE.

Further notes on the development and life history of some teleosts at Beaufort, N. C. Bulletin No. 24, 137 pp., 159 figs.

HOPKINS, A. E.

Experimental observations on spawning, larval development, and setting in the Olympia oyster, Ostrea lurida. Bulletin No. 23, 64 pp., 41 figs.

The following papers were published by members of the staff of the Division of Scientific Inquiry during the year 1937, outside of the Bureau of Fisheries series:

DAVIDSON, FREDERICK A.

Migration and homing of Pacific salmon. Science, vol. 86, No. 2220, pp. 55-56. Ellis, M. M.

Pollution and aquatic life. Proceedings, Second North American Wildlife Conference, pp. 653-658.

Bonneville Dam and the protection of the Columbia River fisheries. A report of the Commissioner of Fisheries transmitting, in response to Senate Resolution No. 113, a survey of the facilities for the passage of salmon at Bonneville on the Columbia River with recommendations for the conservation and the preservation of the fishing industry. July 22, 79 pp.

Progress reports of the investigations conducted by the various sections, prepared in the main by the section heads, are given in the following pages.

# NORTH ATLANTIC FISHERY INVESTIGATIONS

WILLIAM C. HERRINGTON, in charge

In many respects 1937 was a disappointing year in the New England vessel fisheries. After a steady increase since 1932 in both quantity and value of catch, 1937 witnessed a decline of 6 percent in catch and 12 percent in value below the previous year. The decline in catch is particularly noteworthy, occurring as it did in spite of the increase in size of the fishing fleet through the addition of 10 large otter trawlers and several smaller vessels. The decrease in value per pound also is worthy of comment in view of the fact that meat prices during the same period were at their highest in many years.

Although the catch of several species, notably cod and flounders, increased, this gain was more than counterbalanced by declines in the catch of mackerel, whiting, redfish (rosefish), haddock, and pollock. The decrease in whiting and redfish possibly was a reaction from the meteoric expansion of these fisheries during the previous year, but the drop in mackerel and haddock was due to other than economic

causes.

showed a slight increase.

The most outstanding event both economically and biologically was the relative failure of the mackerel fishery. The 1937 catch reached but 14 or 15 million pounds, a decline of about 65 percent below the catch of the previous year. This scarcity was reflected in the price which increased from an average of 2.8 cents a pound in 1936 to 5.1 cents a pound in 1937 (Boston, Gloucester, and Portland landings). All other species decreased sharply in value except redfish which

In spite of the increased fishing capacity of the groundfish fleet from the construction of new boats, the haddock catch continued the decline begun in 1936. Preliminary calculations indicate that this decrease was due to a decline in catch per unit of effort of about 20 percent on Georges Bank and 26 percent on the Nova Scotian banks. This is the first decline on the former since 1933, and the third consecutive year of decrease on the latter. The total catch declined 5 percent from the 1936 total of 144,000,000 pounds.

General adoption of the Bureau's recommendation of large-meshed or "savings" gear for otter trawls took place in the spring of 1937 as the result of a voluntary agreement among the operators of New England otter trawlers. Owing to the lack of personnel, it has not been possible to make further observations on the use and performance of this gear, but reports indicate favorable results when properly used.

As during 1936, biological investigation was confined primarily to haddock and mackerel, while many other important species could not be covered owing to limited personnel and facilities. Among these were cod, second in importance only to haddock in the New England fisheries; redfish, flounders, pollock, and whiting. Additional knowledge of the yield and life history of all of these species is needed, for they are being subjected to increasingly intensive exploitation.

The exploratory shrimp trawling carried on in the Gulf of Maine in 1936 (described in Memorandum I-57) has not yet resulted in the development of a commercial fishery of any size. Occasional reports indicate growing interest in this resource which may eventually lead to the development of a considerable small boat fishery during certain

seasons of the year.

Works Progress Administration Project No. 165–14–6999, begun in 1936, was terminated in July 1937. When the project came to an end, the mackerel and shorefish work was about completed, but considerable work remained on certain parts of the haddock project and on the compilation and charting of the data assembled on the project

covering statistics of the New England fisheries.

The headquarters of the North Atlantic Fishery Investigations has remained in Cambridge and Boston, Mass. Harvard University has generously provided the staff with space and facilities in its Biological Laboratories. The cooperation of the Woods Hole Oceanographic Institution is gratefully acknowledged, as is the personal advice and interest of Prof. Henry B. Bigelow. The assistance and cooperation of fishermen and dealers in providing the use of their records, and in other ways, is also acknowledged with pleasure.

# HADDOCK

The year 1937 witnessed no striking new developments in the New England haddock fishery although several trends indicated in earlier years became more pronounced. The increase in the otter-trawl fleet begun in 1936, continued with the addition of 10 large otter trawlers. These additions were partly counterbalanced by the withdrawal from active service of several old steam trawlers, but the total fishing capacity of the fleet was greater than at any other period in its history. In spite of this increased fishing effort, the total groundfish catch landed at Boston, Gloucester, and Portland by vessels of 5 net tons or over dropped about 2 percent from the all-time high of 386,000,000 pounds reached in 1936, and the catch of haddock, as noted above, decreased 5 percent from the 1936 total of 144,000,000 pounds. This decrease in haddock landings also was accompanied by a decrease in average value to the fishermen from 3.1 to 2.8 cents a pound with the result that the total value of the haddock catch dropped about 14 percent below that of the previous year.

The past year also showed a continuation of the trend toward a broadened base for the otter trawl fishery in terms of kinds of fish utilized, resulting from the lack of sufficient haddock to supply an expanding market, the use of modern processing methods which prepare the various species in equally convenient form, and changes in the market as the result of the above factors. In 1929, 66 percent of the catch of the groundfish fleet consisted of haddock. By 1937, owing largely to the increasing catch of other species, the proportion of haddock had decreased to 36 percent, while redfish had increased from 0 to 15 percent, and cod, pollock, whiting, and flounders showed smaller increases. Partly as a result of this shift to other species during periods when haddock were scarce, and partly owing to the increased use of frozen fillets, haddock price fluctuations have been greatly reduced.

This fundamental change in the groundfish market should have significant repercussions in the fishery for haddock and other species. In the past, with the mass production market concentrated on one kind of fish, it was possible for the commercial fishery to reduce the average abundance of that species far below the level of others found in the same general region. With the present development of a less specialized market this should no longer occur. Increased scarcity of one species will cause a shift in fishing intensity to another before severe depletion occurs, with the result that the abundance level of the

various marketable species will tend to fluctuate together.

With the above developments the haddock problem in many respects becomes a groundfish problem, for it no longer will be possible to explain or predict fluctuations in the haddock catch on the basis of the haddock population alone. The general condition of the other major commercial species must also be known. This extension of the catch analysis is one of the most pressing requirements of the investigation. Continued progress toward the accurate prediction of catches and rationalization of the fishery requires understanding of

the abundance of cod, redfish, and pollock as well.

Progress of investigation.—The haddock investigations are designed primarily to provide an accurate measure of the extent and cause of changes in abundance and to develop a practical plan of exploitation that will maintain the yield at the optimum level. Accurate figures of total haddock catch are collected for each major fishing area in cooperation with the Division of Fishery Industries. Assembled records of total catch show that haddock landings at principal New England ports increased from about 60,000,000 pounds in 1921 to nearly 250,000,000 pounds in 1929, dropped to 140,000,000 pounds in 1932, and have since then fluctuated about that level.

The relative abundance of haddock from year to year is being studied through the detailed analysis of the catch records of three groups of trawlers. This yields an accurate measure of their average "catch per day's fishing." Extensive and detailed analysis of otter trawl catch records demonstrates that in the Georges Bank-South Channel region the catch per unit of effort more than doubled between 1923 and 1927, then dropped precipitously to one-fifth that value in 1931. Catch per unit then gradually increased to a level in 1936 nearly double that found 5 years earlier, but little more than one-third as high as during the 1927 period.

Fluctuations in total catch have been due to changes in the abundance of haddock on the banks and to changes in the amount of fishing effort expended. Fluctuations in abundance, as measured by "catch per day," have been primarily due to differences in the numbers of young haddock produced during successive spawning seasons, combined with a rapid depletion of the stock of older fish due to the very

intensive fishery.

Growth rate on the various fishing grounds is studied through the analysis of length frequency data and scales regularly collected on the Boston Fish pier and at sea on commercial trawlers and on research vessels. Because of the limited amount of time available for the study of growth rates only general conclusions may be drawn. The growth rates on the different parts of Georges Bank differ considerably among themselves, but when samples are considered enmasse, the growth is seen to be considerably greater than on the Nova Scotian banks, especially for the younger sizes. Over the entire haddock range covered by the New Egland fishing fleet growth appears to be greatest in the South Channel region and least on

Banquereau.

Passive migrations of haddock eggs and larvae have been studied through the systematic sampling with plankton nets of the egg and larval population in the South Channel-Georges region and through the determination of ocean currents by the use of drift bottles, water temperatures, and densities. It has been found that the principal spawning center is on eastern Georges Bank, with a smaller one in South Channel. The eggs from eastern Georges Bank drift to the southwest, where they hatch, part of the larvae being caught in a current circling to the northeast around Georges Shoals. young fish presumably go to the bottom in this region, and by the end of the winter are found principally on southeastern Georges The eggs and larvae not caught in the northeast current are carried to the westward toward Long Island, where they presumably perish, for no young haddock have been found on the bottom in this The data indicate that no appreciable number of eggs and larvae reach Georges from other banks, demonstrating that this area is a self-contained unit insofar as the supply of young is concerned.

Most of the information concerning the active migrations of older fish is derived from analysis of length and age data. Results indicate that there is no movement of young haddock between Georges and the Nova Scotian bank, but that a limited intermixture of the older fish takes place. For practical considerations the populations of the areas east and west of the Fundian Channel may be considered

ndependent.

The relative abundance of year classes is being determined through the age analysis of the commercial catch and of material collected on the Atlantis trawling trips in 1935 and 1936 through the cooperation of the Woods Hole Oceanographic Institution. The haddock work is urgently in need of facilities for continuing such deep sea trawling to determine the abundance and distribution of 1-, 2-, and 3-year-old haddock, as it is becoming more and more evident that major changes in both the distribution and size of the catch depend on the abundance of these smaller sizes during the previous year.

During 1937 the haddock work continued under the direction of W. C. Herrington, assisted by J. R. Webster and H. M. Bearse. Principal effort was concentrated on the collection of accurate data showing the total amount of haddock taken from each fishing ground, the continuation and improvement in accuracy of the determination of catch per unit of fishing effort, the analysis of catch records going back to 1914, to obtain a similar measure of haddock abundance for comparison with the present trend, analysis of length and scale data to determine growth rates and mass intermigrations, and analysis of material collected on *Atlantis* trawling trips in 1935 and 1936, to show changes in the composition of the population on Georges Bank, sex ratios, growth rates, and migrations.

Field work to a large extent was limited to the Boston Fish Pier, where Mr. Bearse continued the collection of data. Information for each boat and trip showing sailing date, landing date, and areas fished was supplied to the Division of Fishery Industries and incorporated in its statistical reports. In addition to the above field work, trips were made on the trawlers Winchester and Fordham to obtain catch

data.

Although all of the statistics for 1937 are not yet available, it is possible on the basis of 8 months' data to estimate the changes in the haddock population that affected the commercial fishery in 1937. The abundance as indicated by average catch per day in the Georges Bank region decreased about 20 percent, while that on the Nova Scotian banks decreased about 26 percent. As a result of the relatively poorer yield from the latter area, the fleet spent an increasing proportion of its fishing time on Georges Bank, and this together with the increased fishing capacity resulting from the construction of new boats, resulted in an increase in the total catch on Georges Bank from 75,500,000 to 83,000,000 pounds, a rise of 10 percent, in spite of the decreased abundance. Apparently the decrease in the proportion of time spent on the Nova Scotian banks about equalled the increase in effort from the addition of new boats, for the decline in catch (25 percent) approximated the decline in catch per day (26 percent).

The downward trend in abundance on Georges Bank followed moderate increases in 1934, 1935, and 1936, while on the Nova Scotian banks the downward trend marked the third year of decline, a total drop in catch per day (by weight) of about 33 percent since 1934. The year 1937 also marked the return of the bulk of fishing activities to Georges Bank. During the 1929 period this area supplied around 90 percent of the total haddock catch, but this share had dropped to 30 percent in 1934, as the fleet sought more distant fishing grounds to maintain its catches. Following 1934, the fishery again swung back to Georges as the result of decreasing abundance on the Nova Scotian banks and the relatively better conditions on Georges, with the result that the proportion of the catch supplied by the latter increased from 30 percent in 1934 to 40 percent in 1935, 52 percent in

1936, and 61 percent in 1937.

Analysis of records prior to 1923 to yield catch per day figures comparable to present data has proceeded, but is not yet complete.

Further analysis of the data collected on Atlantis trawling trips in 1935 and 1936 in conjunction with data from the commercial catch

indicates that the exploratory trip in 1935 did not provide a representative sample (in respect to age and size composition) of the Georges Bank population, but that the 1936 data were much better. The work clearly demonstrates that the commercial fishery does not sample all sizes of marketable haddock in equal proportions. Owing to the price differential between large and scrod haddock, the former generally are over-sampled. It is concluded that field work of the kind carried on from the Atlantis is absolutely essential to supplement data from the commercial catch. Such work makes possible an estimation of the relative abundance of 1-, 2-, and 3-year haddock which are not sampled by the commercial fishery; provides information concerning the haddock populations in areas not fished by the trawling fleet because the fish are too small or too scattered; and gives some check on the accuracy with which the commercial catch samples the population. In addition, many valuable data are obtined on growth rate, sex ratio, and distribution.

Considerable progress was made in combining and summarizing length-frequency data collected in 1936 and 1937. One-month and 4-month summaries by subareas have been prepared so that the data now are ready to be broken down into age classes. Analysis of scale samples was confined to the Atlantis collections and contributed to the results discussed above. During the work on length frequencies, a careful analysis was made to determine the most satisfactory method for sampling the commercial catch and for combining the samples. The results of this investigation were reported in a paper

read before the American Statistical Association.

Prospects for 1938.—In Progress in Biological Inquiries, 1936, it was stated that in 1937 a moderate decline in catch per unit of effort on Georges Bank might be expected while the total catch should increase somewhat. The catch per unit actually decreased about 20 percent (8 months' data) while the total catch increased 10 percent. For the Nova Scotian banks it was predicted that there would be a considerable decline both in catch per unit of effort and in total catch. The catch per unit actually decreased about 26 percent (8 months' data) while the total catch decreased about 25 percent.

In view of the facts that analysis of 1937 data is not yet completed and that data on the abundance of the 1936 class (which will reach marketable size in 1938) are lacking, it is impossible to make definite predictions for the 1938 season. The catch per day both in the Georges Bank region and on the Nova Scotian banks will undoubtedly be considerably less than in 1937 unless there is a great influx of scrod during the summer and fall (1936 class on Georges Bank and 1934 class on the Nova Scotian banks). Unfortunately, the relative abundance of these classes on the grounds mentioned is not known, for the members of these groups were too small to be taken in significant numbers by the commercial trawlers during 1937 and no boat was available for special trawling trips such as were made on the Atlantis in 1935 and 1936. Unless the 1936 and 1934 classes appear in unusual abundance, it appears that the decline in catch per day will be sufficient to cause a considerable drop in total haddock catch in spite of the increase in the size of the fleet.

### MACKEREL

Although statistics for the 1937 mackerel season on the Atlantic coast are not completely assembled, a fair estimate of the total United States vessel catch lies between 14 and 15 million pounds. the poorest catch since 1922, when landings by vessel fishermen were about 9,000,000 pounds. The 1937 catch falls about 65 percent below 1936, when some 40,000,000 pounds were landed at eastern ports.

This great decline brought serious consequences. Many fishermen who usually depend upon the mackerel fishery for their livelihood during a great part of the year were forced either to engage in some other fishery, such as dragging, or to continue after mackerel at negligible profit. The majority of the fleet adopted the latter In either case, the financial return was reduced greatly under expectations. Another aspect of the situation is well illustrated by cold storage statistics. During the previous 5-year period, the New England and Middle Atlantic cold storage holdings of mackerel reached a maximum in September or October. This reserve, which averaged 10,000,000 pounds, was built up during summer and early fall when prices were low. In October of 1937, on the other hand, less than 2,000,000 pounds were in storage, and even after continued speculative purchases at high prices, the maximum holdings attained were but 3,000,000 pounds by the end of the year.

In the light of developments during 1937, the necessity for an accurate mackerel catch forecast stands out more than ever before as an important fisheries problem. The biological basis for any successful prediction of catch must be a sound knowledge, not only of the mackerel, but also of its environment. Acquisition of such knowledge has occupied the principal attention of the mackerel investigators during the past 10 years and a report is now in preparation covering results of the work through 1936. Briefly summarized, they are as follows (O. E. Sette, Report to the North American Council on Fishery Investigations, September 1937):

Winter home.—The species winters along the edge of the continental shelf, most probably from the offing of Chesapeake Bay to the Fundian Channel, and possibly as far east as Sable Island Bank. When in the winter habitat, mackerel probably are in mid-depth

rather than on bottom or at the surface.

Migrations.—The population migrates in two divisions: a southern contingent that moves shoreward between Chesapeake and Delaware Bays in April, thence northeastward along the coast to the Gulf of Maine, in the western part of which it spends its summer, returning southward around Cape Cod in late October; and a northern contingent that moves shoreward toward the coast of southern New England in late May, thence northeastward across the Gulf of Maine, along the Nova Scotian coast, and into the Gulf of St. Lawrence where it spends the summer. This division is believed to emigrate along the Nova Scotian coast and through the western portion of the Gulf of Maine (where it supports an important November drift-gill-net fishery) and out to sea past Cape Cod. The northern contingent, when migrating along the Nova Scotian coast in the spring, may be joined by additional members from directly offshore and when leaving in the fall may lose members in an offshore direction if any winter as far eastward as the outer edge of the Nova Scotian banks. Both southern and northern contingents leave stragglers behind them along their migratory routes so that some mackerel, usually the smaller adolescent individuals, populate the coasts of southern New England and Nova Scotia, even though the main bodies are in the Gulf of Maine and the Gulf of St. Lawrence.

Horizontal distribution.—During the summer sojourn mackerel predominantly inhabit the open waters over the inner part of the continental shelf. Important numbers are regularly found neither in enclosed bays nor in far offshore positions. The waters of the deep central portions of the Gulf of Maine are particularly avoided and catches are only occasionally made over the offshore banks. Larger individuals tend to be farther offshore than smaller ones.

Vertical distribution.—The marked thermocline established in spring and persisting through summer forms the lower boundary of mackerel distribution, the underlying colder water imposing an effective barrier to downward movement. Variations in position and intensity of the thermocline affect the success of the fishery.

Schooling habits.—Mackerel are usually aggregated in dense schools—a form of association that probably is advantageous in feeding on plankton. The lesser swimming ability of smaller individuals, resulting from the relation between volume of muscle and surface area, causes a marked but variable schooling according to size.

Feeding habits.—The American representatives of the species feed almost entirely on plankton, but additional observations are needed relative to large offshore individuals, which, like their European relatives, may subsist on small fishes during the late summer and autumn months.

Spawning.—The inner portions of the continental shelf between Cape Hatteras and Cape Cod form the most productive spawning ground; next is the southern half of the Gulf of St. Lawrence. Spawning in intermediate areas is of slight importance excepting perhaps the southern part of Massachusetts Bay which has high concentrations of eggs in spite of its small area. Spawning takes place in April and May south of Cape Cod, in May and June in Massachusetts Bay, and in July and August in the Gulf of St. Lawrence.

Early life history and growth.—Eggs hatch in 3 to 8 days, depending on temperature. The earliest post-planktonic individuals to be found during the course of the investigations were 2 to 6 inches long in the latter part of July. By the end of the first season mackerel are 7.5 to 10.25 inches long; by the end of the second season, 10 to 14 inches long. Thereafter, growth is slower. By the tenth year mackerel average about 18 inches in length, and weigh 2 to  $2\frac{1}{2}$  pounds.

Although many of the more important features of mackerel biology are fairly well understood, and by themselves will furnish a reliable catch forecast in some years, the fact that environmental conditions exert a profound effect upon the actual catch was well illustrated this year. In the annual prediction for 1937, it was estimated that the abundance of mackerel would be about 80 percent of the 1936 level. The actual catch, however, reached about 35 percent of the 1936 level. The difference appears to have been due chiefly to inability of purseseine fishermen to find fish in the usual localities.

The spring run fell under expectations, but not to an alarming degree. During summer, the decrease was more pronounced. Purse seiners found schools unusually scarce and close to shore, their operations being hampered at times by shallow water. At the same time, shore-trap operators enjoyed their best mackerel catches in many years. The mackerel populations were not wholly centered along the shore, however, since otter trawlers on Georges Bank caught unusual numbers of them incidentally throughout the summer, evidence of a relatively large offshore dispersal. Furthermore, many observers noticed a scarcity of Calanus, the favorite "red feed" of mackerel, on the usual mackerel feeding grounds. This may explain the scarcity of mackerel in these areas. Reasons for the scarcity of Calanus are not known but unusually warm ocean temperatures offer a possible explanation.

The fall mackerel season showed evidence of improvement in October, and in November the landings, though small, were greater than in the previous year. This improvement preceded an event which made fishing history, a continuation of mackerel seining into

January 1938.

Mackerel work during 1937 was continued under the direction of O. E. Sette. Field data were collected principally by F. E. Firth. These comprised 534 interviews to obtain information on individual trips, measurement of 36,139 mackerel for length frequency analyses, and collection of 1,135 scale samples. In October, O. E. Sette, who had directed the North Atlantic investigations and conducted the mackerel work since 1926, was transferred to the Pacific coast. It is expected that a comprehensive report covering the results of his investigation will be ready for publication during the coming year. J. R. Webster has been assigned to continue the mackerel work in 1938.

# MIDDLE AND SOUTH ATLANTIC FISHERY INVESTIGATIONS

R. A. Nesbit, in charge

The fisheries of the Middle and South Atlantic States offer an opportunity to realize substantial benefits from scientifically controlled management. It is difficult to escape the conclusion that these fisheries have been exploited inefficiently for many years. In spite of developments which might be expected to increase production, such as the expansion of markets through population increase in the Seaboard States, technical improvements in fishing methods and distribution facilities, extension of intensive fishing activities to areas not previously fished, more intensive fishing on the older grounds, and development of markets for species not previously utilized, the production of food and game fishes has not merely failed to increase but has actually declined during the present century.

This situation is undoubtedly an illustration of the modern theory of fishing exploitation which states that in the long run a fishery of moderate intensity will, by maintaining a high level of abundance, produce an annual crop at least as great and usually greater than an excessive fishery, and at a much lower cost. Statistical records show that the less intensive fishery of 40 years ago actually did pro-

duce more than the fishery of the present day. Since the only source of real income from the fishery is the difference between the sale price of the product and the cost of production, it follows that a moderate, hence low cost, fishing could provide employment either for the present number of fishermen at a higher income level or for more fishermen at the present standard of income, and in either case with a substantial reduction in the hours of labor per fisherman per year.

In addition to the economic gain to the commercial fisheries, restoration and maintenance of high levels of abundance will also improve angling conditions. Many species, including bluefish, weakfish, fluke, winter flounders, sea bass, scup, tautog, kingfish, croaker, striped bass, tuna, and swordfish, support a great recreational fishery which

is growing in importance.

Although the objectives of fishery management in this region are clear, the problem of devising and enforcing measures to accomplish them is extremely difficult. A horizontal reduction in fishing activity in all localities and by all methods of fishing would not lead to maximum efficiency, nor would a return to the fishing and distribution methods of 40 years ago. The gross yield of the fishery is the aggregate of the yields of many species which differ greatly in life histories and habits and in their capacity to withstand the effects of the fishery. Most of the important types of gear, such as pound nets, otter trawls, purse seines, haul seines, and gill nets, take more than one species. Consequently, modifications of fishing methods and fishing intensity which would lead to maximum efficiency for one species might result in inefficiency through incomplete utilization of other species.

It is the object of the scientific investigations of the Bureau to devise equitable and practical means of maintaining adequate numbers of spawners and of harvesting the crop produced by each year's spawning as nearly as possible at the size and age at which the greatest yield in pounds can be taken with the minimum fishing

effort, i. e., at the lowest cost.

For the present, at least, the most profitable field for the application of fishery management practices appears to be that of eliminating as far as possible the present wide spread destruction of fish too young to be marketable and marketing of fish which would be more valu-

able if allowed to grow to larger sizes.

It is recognized that many difficulties exist. The diversity of sizes and shapes of the several species taken by pound nets, seines and otter trawls renders it difficult to permit the escape of undersized fish by increases in the mesh size of the netting, for meshes which allow the escape of the young of large species may also allow legitimately marketable sizes of smaller species to escape. In some localities at least, increase in the sizes of mesh would result in great inconvenience in fishing through the gilling of certain sizes in the meshes. However, many species, including scup, sea bass, striped bass, winter flounders, and fluke, are sufficiently hardy that the majority would survive the handling incident to sorting. Steps should be taken to require that catches by pound nets, seines, and otter trawls be sorted as soon as they are taken from the net, wherever and whenever conditions of weather and tide permit, even at the

cost of some inconvenience and delay in removing catches from

the nets.

If this line of attack on the conservation problems of the region be adopted by even a few of the several States in which jurisdiction over territorial waters is vested, the expected benefits will not be wholly nullified by failure of adjacent States to adopt similar measures. In this respect the proposal differs from plans to restrict the catch of the larger and more desirable market sizes, for unless closely coordinated action be taken by all of the States concerned restriction in a single State may be expected to stimulate fishing in adjacent States so that little or no reduction in the catch of the larger sizes from the

migratory population as a whole may be expected.

Until October 1937 scientific activities in the Middle and South Atlantic region were administered from the headquarters of the North and Middle Atlantic Fishery Investigations at Cambridge, Mass. In October headquarters were established in the Horticulture Building of the University of Maryland at College Park, Md., under the direction of R. A. Nesbit. The courtesy of the University in providing office and library facilities without cost to the Bureau is gratefully acknowledged. W. C. Neville is carrying on the investigations of shore fishes of the Middle Atlantic States, formerly under Mr. Nesbit's supervision, although Mr. Nesbit is continuing analysis of squeteague data. Field headquarters for study of the shad fishery were established in the Charleston Museum, Charleston, S. C., office and laboratory facilities being generously provided by the Museum. John C. Pearson is in charge of the Charleston office, assisted by Louella Cable, Charles O. Hathaway II, and Oliver A. Duff.

### SHORE FISHES

Field observations of this group of species have been conducted on a greatly reduced scale since 1932, when economies in administration

were effected.

To a large extent this reduction in Bureau activities has been compensated for by increased scientific studies by the conservation departments of several States in the region, working in cooperation with the Bureau's staff. Rhode Island has established a laboratory in Narragansett Bay. The Rhode Island investigators, under the direction of Dr. Charles Fish, Professor of Zoology in the Rhode Island State College, have cooperated in a program of tagging winter flounders and have begun valuable studies of the survival of flounder fry planted by the hatcheries. Connecticut has sponsored an investigation of striped bass, preliminary results of which were published during the New Jersey has undertaken tagging experiments with young striped bass salvaged from condenser screens in Delaware Bay. Maryland has established an effective scientific organization under the supervision of R. V. Truitt, Professor of Zoology in the University of Maryland and director of the Chesapeake Biological Laboratory. Good progress has been made in studies of shad and striped bass. North Carolina has contributed substantially to the cost of the cooperative striped bass investigations conducted by Connecticut.

In New York the biological survey for 1938 will cover the marine district. Mr. Neville has devoted much time in 1937 to conference with the scientists of the New York Conservation Department in order

that the 1938 survey may benefit by the experience of Bureau investigators in this area.

Investigations were conducted by the Middle and South Atlantic

staff during 1937 as follows:

Squeteague.—Two thousand two hundred squeteague, mostly yearlings, were tagged in June and early July in Pamlico Sound, N. C. This experiment was planned to test the view, suggested by scale studies and other observations, that the unmarketable yearlings destroved in Pamlico Sound in the early summer include many individuals spawned the previous year in more northern waters which, if spared, would migrate northward in midsummer. Contrary to expectations, all of the recaptures in 1937 were made locally in Pamlico Sound. This was doubtless caused by the unusually mild Young squeteague spawned in northern localities were not driven as far south as usual during the winter but struck in to the shores in spring much farther north. Unprecedented numbers of yearling squeteague were observed in the spring and summer in New York and the scales of the Pamlico Sound yearlings indicated that few, if any, fish of northern origin were present. This is in marked contrast to the early summer of 1935 when about one-third of the Pamlico Sound yearlings were found to be of northern origin. This tagging experiment will be repeated following a more nearly normal winter.

Scup.—Continued large catches by both winter and summer fisheries indicate that the series of successful spawning seasons which began in 1927 are still continuing. The wasteful practice of destroying large numbers of small scup which persists will accentuate the decline which may be expected to occur when this series is broken.

Progress on Mr. Neville's report on this species was interrupted by additional duties arising from change of headquarters from Cam-

bridge, Mass., to College Park, Md.

Winter trawl fishery.—Mr. Neville spent the greater part of January, February, and March 1937 aboard trawlers engaged in this fishery. His observations indicate that the problem of devising savings gear to spare small fish now wasted by the fishery is so complex that extended experiments will be required. A research vessel equipped for trawling or sufficient funds for charter of a commercial trawler will be required before this work can be undertaken.

Winter flounder.—This species is the basis of a commercial fishery in New York and southern New England and of an important angling fishery in Rhode Island, Connecticut, and New York. Tagging experiments were made in Great South Bay, New York, and in various localities in the vicinity of Narragansett Bay, R. I., to measure the intensity of the fishery and the distribution of the strain between sport and commercial fisheries, and also to determine whether the migrations of these fish are sufficiently limited that conservation regulations by individual States would be practicable. Rhode Island scientists cooperated in the Narragansett Bay experiments. Of the 1.718 flounders tagged during the last week in April 1937, in Great South Bay, 304, or 18.6 percent had been recaptured up to January 1, 1938. About four-fifths of the tagged fish recaptured were taken by anglers and about one-fifth by commercial fishermen. Of the 998 winter flounders tagged in Rhode Island, 128, or 12.8 percent, were recaptured in 1937. Of those recaptured, about three-fifths were

taken by commercial fishermen and two-fifths by anglers. Practically all of the recaptures from both experiments were made within the territorial waters of the States in which tagging was done, indicating that the benefits of any conservation measures adopted by these States will not be nullified by possible failure of adjacent States to adopt equivalent measures.

Since this is one of the hardier species, it is well adapted to conservation measures based on selective fishing, that is, on protection of those sizes which are more profitably allowed to grow as long as the gains from growth more than balance the losses from natural mortality. Further studies of this species will be directed toward an esti-

mate of the most desirable minimum size limit.

### ANADROMOUS FISHES

Striped bass.—In April 1936, an investigation of the striped bass was undertaken through the efforts of the Connecticut State Board of Fisheries and Game. From the first this investigation has been conducted on a cooperative basis. Connecticut sportsmen financed the first 3 months of the work, the State Board of Fisheries and Game then supported the investigation and the American Wildlife Institute contributed a substantial sum in the spring of 1937, when a break in the continuity of the work would have been a severe blow to its prog-In July 1937, the Bureau of Fisheries insured the financial backing of the work for a full year from that date by the employment of Daniel Merriman, who had conducted this work for the Connecticut Board of Fisheries and Game. Several Atlantic seaboard States have contributed to the investigation, and every State from New Hampshire to North Carolina has given its fullest cooperation in some phase of the work. Particularly is this true of Maryland, with its concurrent investigation on the striped bass under Dr. Vadim D. Vladykov. The cooperation of North Carolina, through Mr. Chalk, Commissioner of Inland Fisheries, and of various Long Island fishing clubs has been invaluable. Massachusetts sportsmen have led the way in collecting material on the striped bass through the efforts of David A. Aylward, secretary of the Massachusetts Fish and Game Association, and Oliver H. P. Rodman, editor of Hunting and Fishing.

In colonial times the striped bass was very abundant along the whole Atlantic coast from North Carolina to Nova Scotia. By 1850, it had greatly declined in abundance and in recent years it has been almost a rarity north of Chesapeake Bay. The decline was less marked in the latter locality and in North Carolina, although serious enough especially in the years between 1930 and 1936, to cause

concern.

In 1936, however, unusual numbers of 2-year-old striped bass appeared in Chesapeake Bay and also in New York and in southern New England. Catch records indicate that abundance was greater in the latter localities than at any time during the preceding 50 years. In Chesapeake Bay the large catches of 2-year-old fish were preceded in 1935 by a great abundance of yearling bass, but careful inquiry failed to disclose any evidence of a similar phenomenon in the more northern localities. Tagging experiments showed that many of the 2-year-olds

which summered in Connecticut in 1936, migrated southward in the autumn, some of them as far as the sounds of North Carolina.

These observations indicate that this species is subject to strong year-class dominance and that bass migrate more than was formerly suspected. It is of especial significance that the large 1934 brood was produced in a year when the numbers of mature adults were not only no greater than during the several years preceding, but were also well below average. Consequently, the restriction of the catch of mature striped bass in the interest of augmenting the spawning reserve is of doubtful value even in such localities as Chesapeake Bay, where reproduction is occasionally very successful. It is even more questionable whether protection of mature fish will be profitable in more northern localities where the principal increments to the stocks appear to come from immigration.

This does not imply that the present practice of virtually unrestricted fishing is desirable. Results of tagging experiments indicate that the fishery takes a very heavy toll of successful broods before they mature. It is believed that restriction of the catch of the younger and smaller fish would increase the total yield from each brood and would

incidentally augment the numbers of spawners.

coastal rivers.

Shad.—The gross catch of shad has declined from nearly 50,000,000 pounds in 1897 to less than 9,000,000 pounds in 1935. It is inconceivable that the decline in yield of this choice species does not indicate diminished abundance. Since the shad is not subject to commercial fishing during its period of growth in the sea, the causes of depletion must be sought in human interference with spawning migrations into

The following explanations of diminished reproduction have been offered: (1) interference with spawning by pollution and by obstruction of streams by dams; (2) insufficient numbers of spawners resulting from over-fishing. It is not to be doubted that complete blocking of the Susquehanna River by the Conowingo dam has eliminated a considerable spawning area and it is probable that severe pollution in the Delaware has at least contributed greatly to a virtual disappearance of the shad runs in that stream. On the other hand, a number of rivers which are almost completely free from pollution have shared in the general decline and the Hudson River, which certainly cannot be said to be unpolluted, has staged a most spectacular recovery, the catch increasing from less than 100,000 pounds in 1917 to a yield of nearly 3,000,000 pounds in 1936.

The recovery of fishing in the Hudson River is attributed by the New York Conservation Department to the measures which it has adopted to insure that sufficient numbers of spawners are allowed to escape the fishery. On the other hand, it is believed by many that the shad is highly migratory in its habits and that the increased runs in the Hudson River are merely the result of a desertion of southern

rivers by the stocks which usually seek them.

The former explanation seems more likely but decision must be reserved until the results of tagging experiments, scale studies and other tests of the parent stream hypothesis are available. Consequently, considerable effort will be devoted in 1938 to such observations and experiments.

A preliminary experiment in October 1937, indicated that when young shad about 2½ inches long are marked with internal tags, about one-third survive the initial shock of handling and operation. Unfortunately, the survivors as well as unmarked controls eventually succumbed to unfavorable aquarium conditions so that it is not known whether such tags will be retained indefinitely. Further experiments will be made in 1938.

An attempt will also be made to tag spent shad to determine whether

they return to the same stream each year.

If, as is probably true, the increase in abundance in the Hudson River is the result of regulations which permit an adequate escapement of spawners, the numbers of shad spawning in the Hudson River for the second or third time should be greater than in the seriously depleted southern streams. There are present on some shad scales eroded bands resembling the spawning marks of salmon. If these prove to be spawning marks and if examination of the scales of spent shad indicates that spawning invariably results in the formation of such marks, it is expected that comparison of the numbers and the percentages of "repeaters" in the Hudson River and in southern streams will serve as a basis for judging the effectiveness of such regulations as may be adopted in the southern areas.

A serious obstacle to effective study of the shad fishery is the lack of detailed records of the catch. Better records of the total catch will be needed to convert the estimates of the percentages of "repeaters" into estimates of the actual numbers of spawners escaping the fishery. Records of changes in abundance in terms of catch per unit of fishing effort will be needed in order to follow in detail the results of such regulations as may be recommended. To correct this lack of data, collection and analysis of shad catch records were begun in the Chesapeake region by Ferdinand C. Latrobe and in South Carolina by Oliver A. Duff. The conservation officials of Maryland, Virginia, and South Carolina and the staff of the Bureau's Division

of Fishery Industries are cooperating in this work.

young shad in the same river.

Should it eventually appear that provision for an adequate reserve of spawning adults is the principal requirement for maintenance of abundance, the problem of determining the optimum escapement will be of primary importance. Protection of spawners in excess of the numbers needed for reproduction is obviously wasteful, and inadequate protection prevents full realization of the productive capacity of the resource. An attack on this problem was begun by initiation of studies of early life history of the shad in the Edisto River, S. C., by John C. Pearson, assisted by Charles O. Hathaway II. Louella Cable also began studies of the plankton cycle and the food habits of

It is notable that many years of artificial propagation have failed to halt the decline in abundance of shad. Although it is possible that the decline would have been much greater had hatcheries not been operated, it is desirable to test carefully the effectiveness of present methods of artificial propagation and to experiment with methods of carrying fry to the fingerling size. A beginning on such a program of investigation was made by Mr. Pearson at the Edenton, N. C., hatchery. Pond and laboratory facilities have been placed at his disposal at this hatchery and at the Orangeburg, S. C., hatchery by the Division of Fish Culture.

# SHRIMP INVESTIGATIONS

MILTON J. LINDNER, in charge

During 1937, as in preceding years, the shrimp investigations have enjoyed the cooperation of the Louisiana Department of Conservation, the Texas Game, Fish and Oyster Commission, and the Georgia Department of Natural Resources. The San Patricio Canning Co., of Aransas Pass, Tex., has continued to furnish office space for the Texas investigator. In addition, the City of Gulfport, Miss., during the past year supplied dockage and locker space for the *Pelican*.

There has been a steady addition to the shrimp fishery of new, larger, and more powerful boats drawing larger trawls. This continued increase in fishing effort has been under way for the last several years and is especially evident on the Atlantic coast. The expansion of the fishing fleet, both in size of the individual boats and in their aggregate numbers, has resulted in an increase in its fishing

radius.

The South Atlantic fishery.—The Atlantic fleet, comprised mainly of boats originating in Florida, moves along the coast from North Carolina to Florida with the concentrations of shrimp. As a general rule the summer and early fall fishery is most productive between North Carolina and Georgia. During late fall and winter, however, the shrimp and the fishing fleet are concentrated in the area between St. Augustine and Cape Canaveral, Fla. During the past several years, owing to intensive fishing in more northern areas by the rapidly expanding fleet, the Florida winter fishery has diminished in importance. It appears evident that the greater part of the shrimp are being caught before they reach central Florida. As a result, it is expected that a portion of the Atlantic fleet will move into the Gulf during the winter of 1937–1938.

While the supply shows no signs of serious depletion, the South Atlantic shrimp fishery seems to have reached the maximum of production possible under the present system of management. Although the total catch has not declined, neither has it increased with the augmented fishing effort. Obviously, if more and more gear continue to enter the fishery, the economic stability of each unit will be lowered and a number of the marginal units will find it unprofitable

to operate.

From our present understanding of the shrimp it appears that an increase in the total poundage taken by the South Atlantic fishery can be secured only through better protection afforded the young. The intensified fishery is making greater inroads on the young shrimp, a condition which in turn will cause a reduction in the total pounds landed, even though depletion may not occur. As fishing intensity increases, shrimp fishing will therefore become poorer from the viewpoint of the fisherman.

Tagging experiments conducted by William W. Anderson during the past several years have shown that the larger Georgia and South Carolina shrimp move south into Florida during the winter. During the fall of 1937 shrimp were tagged and released over practically the entire northern range of the fishery in order to determine whether or not large individuals from the northern limits also migrated south to become a part of the Florida winter fishery. Tagged shrimp

were released along the coast from Beaufort, N. C., to Brunswick, Ga. Returns have been secured in Florida from these releases, showing that at least some of the North Carolina shrimp normally migrate to Florida during the winter. Apparently then, the South Atlantic shrimp fishery should be considered as a single unit rather than as separate fisheries, each limited within the boundaries of one of the several States involved. Any regulatory measures or lack of regulations in one section will affect not only that section but other portions of the fishery as well; hence, it is advisable that the States of North Carolina, South Carolina, Georgia, and Florida attempt a cooperative management of their shrimp fisheries, with regulations

as nearly uniform as possible.

Present knowledge of the movements of shrimp suggests many additional questions. What is the fate of the large shrimp that migrate from the northern areas into the Florida winter fishery? Do these shrimp normally return north in the spring to spawn? If there is a return migration, do the shrimp come back to spawn in the locality in which they were reared or is the return more or less haphazard? Is the fishery so intense that practically all the winter migrants are captured before they have an opportunity to return north? What changes can be expected in the future population of shrimp from a more intensive fishery? To what sizes of shrimp and at what seasons of the year can regulatory measures be most profitably applied? Do the shrimp perish at the age of 1 year or is there a breeding reserve in offshore areas beyond the range of the present commercial fishery?

It is expected that the current tagging program will solve many of the problems relating to migrations along the South Atlantic These studies, in addition to yielding positive knowledge of the movements of the shrimp, are supplying data on the intensity of the fishery and the rate of growth of the various sizes of commercial shrimp at all seasons of the year.

The extremely important question of a possible breeding reserve of shrimp more than 1 year of age in offshore waters along the South Atlantic coast cannot be answered satisfactorily however, until exploratory fishing can be performed in the deeper waters. Pelican may be used in such investigations at some future date. Thorough studies of the coastal population show that no breeding reserve is present in any of the coastal areas; therefore if such stock

exists it must be in offshore waters.

The Gulf Fishery.—The most striking development in the Gulf shrimp fishery during 1937 was the large summer and fall run in Louisiana and Mississippi. The run was considerably greater than that of the years immediately preceding and was confined to the above-named States. This run further emphasizes the fact that there are good and bad years with respect to the production of shrimp and that the number of spawners is not the important factor in determining production of young. The 1937 Gulf spring fishery which represents the spawning population was extremely poor and barring the possibility of a breeding reserve of shrimp more than a year old remaining in the deeper waters beyond the range of the commercial fishery, a very small group of spawners was successful in producing

a large number of offspring. It is highly probable that the effluents of the Mississippi River play an important part in determining the

success of spawning.

As stated in several previous reports, there is evidence in the Gulf of an offshore movement of large shrimp during the winter. This migration is comparable in many respects to that of the South Atlantic coast; it differs however, in that it is primarily offshore and outside the present commercial fishing range, whereas the South Atlantic movement is coastwise and within the commercial fishing limits. Early in the year the *Pelican*, a 78-foot Diesel vessel, was transferred to the Gulf for the purpose of making exploratory cruises in order to determine whether or not the winter migrants concentrate in sufficient quantities to permit commercial fishing. Owing to insufficient funds, however, the boat was unable to operate during the fiscal year 1937 and it was deemed advisable to postpone operations until January 1938.

In addition to discovering winter offshore concentrations of shrimp, the work of the *Pelican* should give valuable data on the length of life of the shrimp, whether or not there is an offshore spawning re-

serve in the Gulf, and the extent of the spawning grounds.

Arrangements have been made with Prof. A. E. Parr of the Bingham Oceanographic Institute of Yale University to analyze the salinity samples secured with the *Pelican*. Similar arrangements have been made with Professors H. V. Howe and R. J. Russell of the Department of Geology of Louisiana State University to analyze the bottom core samples which are taken at each trawling station.

The Texas program which has been conducted by Kenneth H. Mosher has been primarily that of sampling the commercial fishery, but during the past 2 seasons, through the assistance of Albert Collier, Marine Biologist of the Texas Game, Fish, and Oyster Com-

mission, tagging operations have been added.

It is known that temperature and salinity affect the behavior of the shrimp, and during the past year it has been determined that tides also enter as a factor. In the vicinity of Corpus Christi, Tex., it was found that better catches of shrimp, as a rule, were made dur-

ing periods of low than of high water.

John C. Pearson, prior to his transfer to the shad investigations, submitted for publication a manuscript describing the larval stages of the common shrimp and those of four other peneids. This basic work will be of considerable aid in determining the extent of the spawning grounds.

### NORTH PACIFIC AND ALASKA FISHERY INVESTIGATIONS

Dr. F. A. Davidson, in charge

The North Pacific and Alaska fishery investigations, with headquarters in the Fisheries Biological Station at Seattle, Wash., are confined mainly to the solution of problems concerning the maintenance and rehabilitation of the salmon and herring fisheries of Alaska and the salmon fisheries of Puget Sound and the Columbia River. All of the major investigations in progress in 1936 were continued in 1937.

# COLUMBIA RIVER SALMON FISHERIES

Investigations of biological and physical conditions affecting the Columbia River fisheries were continued during 1937 by J. A. Craig and A. J. Suomela. Counts of salmon and steelhead migrating over Rock Island Dam in the Columbia River and into the tributary Okanogan and Wenatchee Rivers were formerly part of this investigation. In 1937, however, this work was taken over by the U. S. Bureau of Reclamation and the Washington State Fisheries Department, under the project concerned with the protection of migratory fish at Grand Coulee Dam. The collection, tabulation, and analysis of catch records of the commercial fisheries in the Columbia River was continued to provide data on the annual and seasonal indices of abundance of fish populations in the river system. During the year a report on the history and development of the Columbia River fisheries, including salmon, sturgeon, shad, and smelt, was submitted for publication.

Tagging.—A tagging experiment was conducted for the purpose of obtaining data concerning the spring, summer, and fall runs of chinook salmon which pass through the commercial fishery from May to September, inclusive. The results of such experiments provide data on the minimum distances which the fish travel upstream to spawn, the proportion of the runs which return to hatcheries, the proportion caught by the commercial fishery above the point of tagging and the speed of migration of the runs after entering the river.

In 1936, a total of 1,059 fall chinooks were tagged and liberated between August 16 and September 2. Tagging this season consisted of 21 experiments from May 17 to September 1, inclusive, in which 1,565 chinooks were tagged. Two of these experiments were conducted at a location 1¾ miles above the mouth of the river and the remaining 19 at a location 5¾ miles above the mouth of the river. The runs of salmon were extremely light during the spring and

summer and only a few fish were secured for tagging.

Recoveries of the tagged fish amounted to 381 or 24.3 percent of the total tagged. A few recoveries were taken between the mouth of the river and the point of tagging, but none outside the mouth. A total of 38 tags, or 2.43 percent, were recovered at hatcheries on the Columbia River system. One fish bearing a tag was recaptured in the Toutle River, a tributary of the Cowlitz River. Two tags were observed on fall chinook salmon in the Chinook River but they could not be recovered. The remainder of the tagged fish were caught in the main Columbia River. Tagged salmon were recovered up the river as far as Celilo Falls, 190 miles from the point of tagging.

The results of the experiments in 1937 are now being analyzed. These data, together with the data of the 1936 experiments, will be incorporated in a report to be submitted for publication in the

near future.

Stream surveys.—With the exception of surveys conducted on portions of four of the major tributaries of the Willamette River system in the State of Oregon, Columbia River stream survey activities in 1937 were again confined to the State of Washington.

In north central Washington tributaries of the four major river systems, the Okanogan, the Methow, the Entiat, and the Wenatchee, have been surveyed. Fifty minor streams were also examined. In this area a total of 117 dams of all types were found, of which 32 are permanent structures, and 85 temporary. Three of the permanent dams are obstructions at all times, and 21 are barriers at low water only. The number of dams used for irrigation totals 107, of which 23 are permanent and 84 are temporary in nature. Two dams are used for power, 1 for irrigation and power, and 7 for other purposes. There are 143 diversions, of which 133 are for irrigation, 4 for power, 1 for power and irrigation, and 5 for other purposes. In the 34 streams examined in this area, which are part of the 4 major river systems, it was estimated that 35 percent of the river bottom was suitable for spawning purposes, with approximately four-sevenths of this total available to fishes at all times, and three-sevenths unavailable at low water.

In the south central area, the Yakima River system is the only large stream that has been surveyed to date, although 69 minor streams have been examined. In this survey a total of 163 dams were recorded, of which 40 are permanent and 123 are temporary. One hundred and fifty-nine of these are used for diverting water for irrigation purposes and of this number 38 are permanent and 121 are temporary. Five of the permanent dams are complete barriers, 26 are barriers at low water only, and the remainder are passable to fish at all stages of water level. The number of diversions in this region total 280, of which 270 are used for irrigation, 5 for power, 1 for power and irrigation, and 4 for other purposes. In the 34 streams in the south central area that have been examined, it was estimated that 59 percent of the bottom was suitable for spawning, with three-fifths of this total available to spawning fish at all times and two-fifths unavailable at low water.

The survey of the southeastern area of the State of Washington has been completed. This included the following river systems: the Tucannon, Asotin, and Walla Walla Rivers, and 29 minor streams. There were 112 diversion dams in this area, 32 of which were permanent structures and 80 temporary. A total of 172 diversions were found, of which 160 were used for irrigation, 2 for power, 6 for power and irrigation, and 4 for other purposes. In the 17 streams examined it was estimated that 71 percent of the bottom was suitable for spawning, but of this total only one-third was available to fish at all times, two-thirds of the area being unavailable at low water.

The survey of the southwestern area of the State of Washington has not been completed to date. Thus far, a total of 22 dams have been recorded. They are used for the following purposes: 1 for irrigation, 6 for power, and 15 for other uses.

In the State of Oregon stream surveys were conducted on the middle fork of the Willamette River from the proposed flood control dam site at Lookout Point to Tumblebug Creek; on the McKenzie River from the proposed dam site at Quartz Creek to Tamolitsh Falls; on the North Santiam River from the proposed dam site near Detroit to Big Meadows Camp; and on the South Santiam from the proposed dam site at Sweet Home to House Rock Camp at Sheep Creek. During the survey of these streams 4 permanent dams were found, of which three formed partial barriers and one a complete barrier to migratory fishes.

A total of approximately 2,300 miles of stream have been surveyed in the Columbia River drainage up to the present time. Data

derived from all of these investigations were made available on many occasions to interested individuals and organizations, such as State conservation agencies and the National Resources Committee.

# PUGET SOUND SALMON FISHERIES

Sockeye.—The Puget Sound sockeye investigation was continued

by Dr. George A. Rounsefell.

Daily salmon catch statistics were collected for 1935 and 1936, especially on the Fraser River, where the individual gill net landings were obtained for at least 90 percent of the catch. Daily purse seine landings by boat were obtained for the past 12 years, 1925 to 1936, from Quathiaski, at the northern end of the Gulf of Georgia. It has long been known that a portion of the Fraser River run used the northern route instead of entering through the Strait of Juan de Fuca but no information has been available on its size. In 1936 nearly half a million sockeye were taken in this area. In some years, especially in 1915, 1926, and 1936, the gill nets in the Gulf of Georgia and the lower Fraser River have done much better relatively, than the gear in Puget Sound. Inasmuch as the 3 years in question were extraordinarily warm, it may be possible that the proportion of the run using the northern entrance is largely dependent on temperature. In warm years the sockeye may be feeding farther to the north and so strike the coast in the vicinity of Cape Scott at the northwestern end of Vancouver Island, a fair proportion of the run thus continuing down the inside of the Island.

The usual samplying of the commercial catch was carried on at Anacortes. A feature of the 1937 run was the small average size of the sockeye, which greatly increased the cost of the raw fish to the canneries, as they bought the fish by the piece. The investigation new has available samples of the commercial catch since 1934. The ages of these fish have not been determined pending the completion of this 4-year cycle, but the 1937 scales are now mounted and their reading

is under way.

In 1935 the Division of Fish Culture cooperated with the investigation by planting 76,000 fingerling sockeye (1934 egg collection from the Birdsview hatchery on the Skagit River) in Cedar River, a tributary of Lake Washington, and a like number in Issaquah Creek, a tributary of Lake Sammanish, which drains through the Sammanish River into Lake Washington. It is planned during the spring to watch at the Government locks and fish ladder leading into Lake Washington and on the spawning grounds for adult sockeye, to determine whether the plantings were successful in introducing this valuable species. Judging from the available spawning grounds and the general suitability of these lakes to coho and king salmon and to the land-locked kokanee, they might be capable of supporting a sockeye run of fair proportions.

Since it is the duty of the recently formed International Pacific Salmon Fisheries Commission to make a study of the sockeye runs to the Fraser River system it is not planned to collect additional data on this species. Work on the Fraser River sockeye will be discontinued

as soon as analysis of the data on hand has been completed.

Dr. Rounsefell also carried on experiments in tagging in an effort to develop tags suitable for the salmon work. Experiments with rainbow trout showed that the usual strap tags on the tail or on the jaw were not satisfactory. The Atkins tag through the dorsal fin, however, was well retained and should be tried on a large scale with mature salmon. Its visibility is better than that of the strap tag, an especially valuable feature in searching for marked salmon on the

spawning grounds.

A new type of tag was also developed and tried out on fingerling king and sockeye salmon. This mark, which was named the "internal anchor" tag, consists of three parts: an ordinary flat plate, similar in shape to the nickel herring tag, but preferably smaller; a second small plate of any desired shape, made out of bright-colored celluloid (except bright shades of red which are attacked by other fish); and a short piece of fine silver chain. The long flat plate is inserted into the body cavity with the chain (which is fastened to its center) protruding through the body wall; the second plate of bright-colored celluloid is fastened by one end to the free end of the chain.

In experiments with king salmon fingerlings there was a heavy loss from over-chlorinated city water but after 161 days the survivors were as follows: 36 percent of the controls, 10 percent of those marked with a large anchor and 20 percent of those marked with a small anchor. These fish were between 2 and 3 inches in length when tagged and the mortality was greater than would be expected from

the tagging of slightly larger fish.

After 85 days the survivors of marked sockeye fingerlings are: Controls 100 percent, small anchors 91 percent, large anchors 90 percent, and medium anchors 100 percent.

Coho.—The coho salmon investigation of the causes of the decline in abundance of this important commercial and sport fish and of methods for rebuilding runs of former importance was continued dur-

ing the past year by George B. Kelez.

During the winter and early spring, final returns from the first Samish River marking experiments 2 were obtained. The total return of 3-year fish from the two lots of hatchery-reared native stock, marked and released in 1934, was 469 fish. Of these, 7 recoveries were from 26,150 fingerlings, averaging 47.4 mm (approximately 17/8 inches) in length, marked by excision of a pair of fins in May; and 462 were from an equal number of fingerlings, averaging 101.6 mm (approximately 4 inches) in length, marked by fin excision in November. The ratio of return of the large fingerlings to that of the small ones indicated a much higher survival rate due to the prolonged rearing period.

Final returns from 9,800 fingerlings, averaging 49.2 mm (approximately 2 inches) in length, transferred from the Skykomish River and marked and released in the Samish in 1934 were also obtained during this period. Recovery of a total of 11 fish was made from this experiment, a return considerably greater than that from the smaller native

fish.

Marked fish returning from the experiments carried on in 1935 in Voight's Creek, a tributary of the Puyallup River were recovered during the late fall of 1937. Two lots of fingerlings had been marked by excision of different pairs of fins. The first of these consisted of 50,000 fish reared at the Puyallup River State hatchery, which aver-

<sup>&</sup>lt;sup>2</sup> See Progress in Biological Inquiries, 1934 and 1936.

aged 49.7 mm in length at the time of marking, and the second consisted of 25,000 fingerlings, averaging 49.1 mm in length, transferred from the Green River State hatchery to the Puyallup River immediately before marking. With the run virtually complete, recoveries to date number 28 from the native stock and 8 from the transplanted stock. No recoveries have been made at the Green River hatchery.

A further series of experiments on coho fingerlings have been undertaken during the year to determine the effect of various periods of hatchery-rearing on the return at maturity. This work has been carried on at the Quilcene, Wash., station of the Division of Fish Culture. One lot of these fish was released in September and another in December in the Quilcene River immediately below the station. Additional lots of fingerlings from the same brood are being retained in the hatchery ponds for marking and release during the spring of 1938 at the approximate time of normal seaward migration. Exact costs of rearing and handling are being recorded in order that the comparative results of moderate and long rearing periods may be determined.

Because the number of individual lots of fish which can be marked by excision of a pair of fins is definitely limited by the number of possible combinations, an experiment was undertaken to determine the adaptability of the internal tag for this purpose. The use of these tags has heretofore been confined to relatively large fish and has been attended by the disadvantage that an external mark to indicate the presence of a tag is lacking. Both hatchery-reared and wild coho fingerlings, ranging in size from 43 to 80 mm were obtained and tagged with internal celluloid tags measuring 2 by 12.5 mm and of varying thicknesses. One fin was removed from each fish at the time of tagging and the various lots were held in aquaria for 75 days. Losses in the experimental lots ranged from mortality approximately equal to that of the controls to 75 percent greater than that of the controls.

An operation on a larger scale was then undertaken at the Samish River hatchery to test the tags under field conditions. Tags of 0.030 inch thickness were selected on the basis of the previous experiment and the dorsal fin was removed from each fish at the time of marking for external identification. Excessive losses from a fungus infection were encountered with the first lot marked, which was held in troughs inside the hatchery. After treatment with salt baths for some time the remaining fish were removed to an outside concrete pond, where

they were held until there was no further daily loss.

Lots of these fish were released in Friday Creek on October 8, October 20, and December 11. If the results from tagging compare satisfactorily with those from fin marking, greater opportunity for comparative studies of individual lots of fish will be afforded.

Sampling of commercial and sport catches for data on size, sex, and age was continued and stream collections of fingerings were made for additional material on early life history and rate of growth of coho salmon. A comparison of scale samples from various points in Alaska with those from the local runs indicates that an increasing number of fish in northern waters are returning to spawn at the age of 4 years. All scales examined have shown only 1 year of residence in the ocean, the 4-year fish in Alaska having remained in fresh water until their third year.

Little increase in local spawning escapements has been noted in recent years and a considerable decrease in the commercial catch has been evident. Since local populations mature almost exclusively in the third year, the coming season should demonstrate the effect on this species of the removal of fixed fishing gear from these waters in 1935. Unless the beneficial results of this reduction in gear are considerably greater than is anticipated, more stringent measures for securing an adequate spawning reserve of this species must be adopted if a continued decline in numbers is to be avoided.

# KARLUK RIVER RED SALMON

The investigation to determine the extent and causes of the fluctuations in the size of red salmon runs in Karluk River, Alaska, was

continued in 1937 by J. T. Barnaby and A. C. DeLacy.

Operation of a counting weir in the river provides data on the number of adult fish escaping to the spawning grounds. This escapement, together with the daily catches of salmon made by the companies fishing in the Karluk district, is used to determine the total run into the river. The age group composition of the 1937 run was calculated from an analysis of 14,000 scale samples taken throughout the season. This study of the salmon populations spawning in Karluk River is furnishing valuable data on fluctuations in the size of the runs and also on variations in the ratio of return to escapement.

Studies of the relation between the growth rate of young salmon in fresh water and their survival both in the fresh water and in the sea were continued. Samples of seaward migrant young were collected for the purpose of determining the age and length frequencies of the 1937 population. Results thus far obtained from this study indicate a positive correlation between fresh water growth rate and

survival.

During the season an examination of 434,000 adult salmon disclosed more than 2,100 marked individuals returning from previous years' marking experiments. The numbers and ages of these marked fish indicates that the mortality rate of salmon while in the ocean is fairly constant. The slight variations which occur in it from year to year are not of sufficient degree to account for the great variations in the total survival of these fish from one generation to another. It is evident that the wide fluctuations in the ratio of return to escapement are due primarily to variations in the natural conditions affecting survival in fresh water.

Studies of the food available for young salmon in fresh water entailed a chemical analysis of the waters of Karluk Lake and its tributary streams as well as the sampling of these waters for plankton content. The phosphorous, nitrate, silica, oxygen, and carbonate content of these waters was determined a number of times during the season. As noted in previous years, phosphorous and silica were the chief limiting factors in the growth of plankton and the associated growth of young salmon which depend upon the plankton

for their food supply.

Predatory species.—The Dolly Varden trout is considered the chief predator of the salmon during their stay in fresh water. Although a considerable amount of money is expended every year by the Territory of Alaska and the various fishing companies in destroying this char, very little is known about the species. Dolly Varden trout inhabit the coastal streams on both sides of the Pacific from California to Alaska and south to Japan. Some spend their entire life in streams, some live entirely in lakes, while others spend part of their life in a stream or lake and part in the ocean. The mature fish vary in size from 6 to over 24 inches in length, depending on their habitat and the population pressure. They are frequently found with salmon eggs, fry, and fingerlings in their stomachs, and consequently their extermi-

nation is desired by most members of the salmon industry.

As these fish are very abundant on Kodiak Island and probably are detrimental there as well as elsewhere to the salmon population, a series of marking experiments were initiated during the past year to furnish some information on the migrations, age, and growth rate of this species. Some of the chars were marked by excising two of their fins; others by insertion of a numbered metal tag in the body cavity and excision of the adipose fin so that they could be easily identified when recaptured. Three experiments were started at Karluk and two at Red River, a stream entering Shelikof Straits about 35 miles south of Karluk. In the Karluk experiments chars were marked in the Karluk River during their migration to and from the ocean and in Karluk Lake. In the Red River experiments chars were marked during their upstream and downstream migration.

Fish from only the first experiment of each series (those on downstream migrants) have been recaptured to date, but recoveries will probably continue for 2 or 3 years. The information obtained from

these experiments to date is as follows:

1. Of the chars marked at Karluk in June as they were migrating to the ocean, over 12 percent were recaptured between July 17 and September 9, while on their return migration upstream. Of the chars marked in the first Red River experiment 18 percent were recaptured between July 12 and August 18 as they were migrating upstream. Thus, an appreciable percentage of the chars which migrated to the ocean in the spring returned to their home-stream in the fall of the same year.

2. Marked chars from the Karluk experiments were recaptured in salmon traps in the vicinity of Uganik Island over 45 miles away from the point of tagging and marked chars from the Red River experiments were recaptured in Uyak Bay over 60 miles from the point of tagging. These data show that after entering the ocean some of the chars wander a considerable distance away from their

home stream.

3. That some straying of chars from one stream to another occurs was proven by the recovery of Karluk marked fish at Red River (5 percent of the total recoveries) and Red River marked fish at Karluk (0.6 percent of the total recoveries). Because of differences in fishing regulations, the difference in the amount of straying may not be as great as the figures indicate. Fishing operations are carried on as close to the Karluk River as 100 yards, whereas fishing is prohibited within 1 mile of Red River.

4. These fish grow very slowly during the time spent in the ocean. Although many of the Karluk and Red River chars attain the same length as red salmon, the latter, when in the ocean, grow approximately 6 centimeters (2% inches) a month during June, July, and August,

while data obtained from the marking experiments indicate that the chars grow only about one centimeter a month during this period. Hence, it appears that these fish have a relatively long life span, a supposition which is, in a measure, confirmed by the otolith readings.

Both scales and otoliths have been examined and it has been found that the scales are virtually useless as a means of age determination, and that the otoliths, while of some value, are not altogether satisfactory. This difficulty makes the study of the life history much more complicated and other methods of age determination are being tried.

At Karluk Lake it was noted that chars take a very heavy toll of red salmon fry in the spring at the time the young fish are entering the lake from the spawning streams. However, during the summer and fall relatively little damage is done to the salmon populations by these chars. They have been caught by means of seines and gill nets, and only rarely was one found that had been feeding on salmon fingerlings. Although salmon eggs do comprise a large part of the diet of these fish, it was noted that the chars were feeding almost entirely on floating eggs displaced by the spawning activities of the salmon and these eggs would die whether they were eaten or not. An analysis of stomach contents of chars in Karluk River showed that the chars in the river were not feeding on seaward migrants.

# PINK SALMON

The pink salmon investigation in southeastern Alaska was continued in 1937 by Dr. F. A. Davidson and Samuel J. Hutchinson. The investigation, as in the past, covered numerous pink salmon research problems. Activities were about equally divided between the summer field work in Alaska and the compilation of scientific data at the laboratory in Seattle. The summer field station at Little Port Walter, Alaska, was operated for its fourth consecutive year, remaining in active operation throughout the summer from May 20 to September 20.

The runs of pink salmon in southeastern Alaska during the 1937 season were comparatively light in practically all districts. The total pack of canned salmon was below average but the proportionate take of the total population was as great, if not greater, than in previous years. Catch statistics and studies of escapements into the streams for each district show that in the majority of cases the spawners were insufficient in number to make adequate use of all the available spawning ground afforded throughout the region. In 1937, the rainfall was in excess and most streams provided suitable water conditions for that portion of the population that successfully escaped the intensive commercial fishery.

All through Alaska the trend is toward cannery modernization and increased capacity. As a result the amount of fishing gear is expanding in an effort to increase the take of raw material. It is clear that the saturation point has been reached in all districts in southeastern Alaska and that the industry must, to maintain itself, be content with a smaller average pack per plant if it is to continue in the future. The problem facing the production of salmon in Alaska is nothing more than a farming problem. Seed must be planted if a crop is to be produced, and part of the crop produced must be conserved for seed. The spawning grounds are of limited size, tending to decrease rather than increase, thus making it impractical to think of the salmon resources as an ever increasing commodity.

No tagging experiments were conducted in southeastern Alaska during the summer of 1937, owing to the lack of suitable equipment and funds. The returns from the 1935 and 1936 taggings were studied and a detailed report has been submitted showing the migration routes of pink salmon through Clarence Strait and adjoining waters. It is shown that fish tagged at various time intervals during the spawning migration are bound for widely separated areas. Knowledge of this change in migration as the season progresses provides an explanation of the seasonal shift in the fishery and therefore aids in the establishment of the various boundaries for each district. This tagging report covers both the odd and even year groups and indicates the peculiar migration characteristics of each population.

Weir counts taken at Little Port Walter this year gave the second set of returns from a known even-year escapement and the first returns from a known odd-year escapement. A total of 7,085 pink salmon from the 1935 spawning population were counted through the weir from August 16 to September 10. Previous weir count totals consisted of 6,952 pink salmon in 1934, 6,073 in 1935, 5,164 in 1936, and 7,085 in 1937. The 1937 escapement is a 17 percent increase over the 1935 spawning population, while the 1936 returns were a 26 percent decrease under the 1934 population. Causes for such fluctuations can only be determined through a study of natural and imposed mortality from one point in the life cycle to the corresponding point

in the life cycle of the following generation.

The sex of the individuals composing the run was determined as the salmon passed through the weir. This was accomplished with the aid of a specially constructed pen just above the counting gate which enables the observer to determine and record the sex of the individual fish as they pass through. In this stream males predominate at the beginning of the season, the ratio in some days running as high as 90 percent. This excess of males continues until the run is about three-fourths complete at which time the ratio stands at 2 to 1. During the last quarter of the run the females increase in abundance to such an extent that the ratio of sexes for the season as a whole is balanced. Factors influencing sexual development were observed throughout the season and actual weights of the gonads were taken at various intervals to determine percentage change in weight of sexual products over body weight.

Egg counts were taken to determine the average egg deposition that could be expected for the 1937 run. The average number of eggs produced per female in 1937 was 2,059, which resulted in the deposition of approximately 7,293,000 eggs in the gravel beds of the stream.

Three samples of the run were taken during the season for racial analysis measurements. From 26 body measurements taken from each individual a number of comparisons are made to determine the significance of individual variation. The continuation of racial analysis is expected to provide a method of segregation of various populations which will aid in formulating regulatory measures for future conservation.

Cooperative work with the National Canners Association of Seattle, Wash., carried on for the third consecutive season at the station, consisted of a study of the physical and chemical changes occurring in the pink salmon run at Little Port Walter. Daily

samples of pink salmon taken from the experimental trap in the bay were weighed, measured, and a proportional cut from each fish was canned. The canned samples have been turned over to the National Canners' Association for tests to determine the chemical changes that take place as the season progresses and as the salmon near sexual

A cooperative observer's meteorological record was maintained at Little Port Walter to secure information on a number of weather conditions that are important elements in the salmon's environment. A monthly average of 18.16 inches of rain fell at Little Port Walter during 1937, making a total of 217.90 inches for the year. Rain was recorded on 248 days. It is not known whether this is an excess as the weather station has only been in operation for the past year and a half. The highest air temperature for the year was 72° F., and the lowest was 16° F., with a yearly mean average of 42.73° F., 58 clear days, 94 partly cloudy, and 213 cloudy days were noted at the station during the past year.

station during the past year.

A paper, "The Geographic Distribution and Environmental Limitations of the Pacific Salmon," embodying discussions of factors coincident with the native and foreign distribution of the Pacific salmon was completed and submitted for publication. In every instance where transplantations have been successful the conditions throughout the new habitat have been similar to those in the native waters, thus indicating that a thorough knowledge of the environmental conditions of a proposed habitat is essential before transplantations of

the Pacific salmon into foreign waters are attempted.

maturity.

# ALASKA SALMON STATISTICS

Collection and compilation of daily catch records from the various types of fishing gear operated by the salmon fishery in Alaska was continued in 1937 by L. S. Christey. With the continued assistance of a W. P. A. project initiated in 1936, a complete collection of all available catch records for the remaining fishing districts in Alaska has been accomplished. Along with past records all current records are collected and the files will be kept up to date in the future.

Compilation of these data consists mainly in determining average daily catches for each type of gear throughout each fishing season. This information gives an insight into the relative abundance of salmon in each of the fishing districts and any change which occurs in the date of appearance of the runs of salmon. During the past year the trap-catch records in both Prince William Sound and southeastern Alaska were compiled for all years on this basis. This information as in the past was used as a basis for recommending changes in the fishing regulations in Alaska in order to provide for the conservation of the salmon resources.

# HERRING

Investigation of the herring fisheries of Alaska was continued in 1937 by E. H. Dahlgren. A temporary assistant was assigned to the recently expanded Prince William Sound and Kodiak districts during the fishing season to obtain data on the size and age composition of the runs in these areas and to bring up to date the statistics of these now important fisheries.

Continuing the migration studies, tagging was again carried on during the spring at the Sitka and Craig spawning areas, which are known to contribute the greatest supply of herring to the commercial catch. In this experiment approximately 14.000 individuals were marked at Sitka and 11,000 at Craig. The electronic detector was again operated in Southeastern Alaska for the recovery of tagged

individuals and 113 recoveries were made during the season.

From these recoveries, together with others made in previous years, the migration habits of the commercially important populations have been established. It is evident that: (1) the fishery in the Cape Ommaney area, from which 60 to 95 percent of the total catch is made, draws almost exclusively from the population which spawns in the vicinity of Sitka; (2) the Warren Island fishery draws from an intermixture of the Craig and the Sitka populations, and a small influx of herring from minor spawning grounds south of Craig at least as far as Rose Inlet, approximately 40 miles south of the major spawning area; (3) the summer fishery conducted on the west coast of Kuiu Island, including Malmesbury, Tebenkof, and Pillar Bays, is composed, as is the Warren Island fishery, of herring from the Craig and Sitka spawning areas; (4) the Douglas Island fishery is supported by the Juneau spawning populations; and (5) the Icy Strait and Tenakee fisheries are composed of an intermixture of Juneau fish with some unknown population, most probably that of the Kootznahoo spawning area.

The herring in the Cape Ommaney fishing area from which the bulk of the commercial catch in southeastern Alaska is made, have shown a marked decline in abundance during the past few years. The measure used in evaluating this abundance is derived by a comparison of the catch per unit of gear per day's fishing with the average catch per day's fishing established over a 9-year period. In deriving these indices, the fleet has been divided into two groups (those of over 35 net tonnage capacity and those under this size) to minimize the effect of the difference in efficiency of the larger and smaller

vessels.

The index for the 1937 season for the larger vessels was 71 compared with 73 for the 1936 season, 140 for the optimum year of 1932, and 62 for the minimum year of 1935. The indices for the vessels not over 35 net tons for 1937 was 75, compared with 60 for the mini-

mum year of 1936 and 164 for the optimum year of 1932.

This continuing low level of abundance, while doubtless due in large measure to an overly intensive fishery, was brought about in part by the virtual failure of the three successive spawnings of 1932, 1933, and 1934, to contribute the normal increment of young fish to the populations. The entrance during the 1937 season of a large percentage of the new age class resulting from the more successful spawning of 1935 may be expected to result in a rise in the level of abundance. This year class, which appeared in large numbers as 2-year-olds in the 1937 catch, may be expected to contribute a large portion of the catch as 3-year-olds during the coming season.

The low catch per unit of gear in the Ommaney area during the 1937 season was due in part, also, to the emigration out of that area of the age group which had supported the fishery during the three previous years, the abundant 1931 year-class. Tagged individuals belonging to this age-class were taken in large numbers in the Teb-

enkof-Pillar Bay area on the west coast of Kuiu Island, increasing the catch in that area, but causing a lower catch in the Cape Ommaney region. Such differential schooling has been observed before, especially when, owing to the failure of a series of spawnings, the population is composed of age groups of marked size difference.

The fishery in the Kodiak area, originally developed for the curing of herring, was expanded in 1935 to one for reduction. With this change in the method of utilization there followed a change in the type and intensity of fishing activity—a change which has resulted in a tremendous increase in the poundage taken from this area. A similar change has occurred in the Prince William Sound district, although the shift from curing to reduction has been more gradual. Owing to limited personnel, adequate collection of data from these areas has lapsed during the past few years. With the rapid expansion of the fishery, however, it was deemed essential that records of the catch and of the size and age composition of the catch again be collected in order that signs of depletion might be detected before the fishery declines to the point of commercial extinction, as it did in these areas in early years.

# PACIFIC PILCHARD INVESTIGATIONS

O. E. Sette, in charge

From relative insignificance in pre-war years, the fishery for the Pacific pilchard, also known as California sardine, (Sardinops caerulea) has grown to enormous proportions, a total catch of over 750,000 tons being landed in the season of 1936–37. This is a quantity three times as great as the annual landings of all other kinds of fish in the Pacific Coast States. Attending the expansion of this fishery has been the growth of public concern over the ability of the resource to provide such large catches without endangering the future supply. In California, where most of the catch is taken, this concern has been felt for a number of years and has been expressed in State regulations placing certain restrictions on the use of this fish for reduction to meal and oil. In offshore waters, beyond the 3-mile limit, floating reduction ships have operated without restrictions—a condition considered intolerable by shore operators and State authorities.

The seeking of Federal legislation intended to place the offshore operations under State jurisdiction brought Federal attention to the controversial situation in California. At the same time the legislatures of Washington and Oregon petitioned Congress for a Federal scientific investigation of the pilchard resource which was being fished with increasing vigor in the waters off their shores. As a result, the appropriations of the U. S. Bureau of Fisheries were increased to provide for a Pacific pilchard investigation. The funds became available July 1, 1937, and before the end of the year a staff headed by Oscar E. Sette was detailed to the investigation. The kindness of Stanford University in providing generous laboratory space has led to the establishment of headquarters at a point centrally located with respect to the fishery. Since this investigation lies in a field in which the several States, notably California, are conducting important research, their cooperation in formulating a program and in furnishing data has been of great value.

The first months of the investigation have been devoted to a preliminary reconnaissance of the problem. The basic questions are: (1) Do the fisheries of various localities draw upon one population or upon several self-perpetuating populations? (2) What intensity of fishing will provide the maximum yield of fish of greatest commercial value from each successful year-class? (3) What intensity of fishing will permit survival of a spawning stock adequate to produce successful year-classes?

The first question is being investigated by California, Oregon, Washington, and British Columbia, by the tagging method. It has already been proven that some individuals migrate long distances from Southern California to Washington and vice versa. Whether this represents a small percentage of mixing of the population along the entire coast remains to be seen. It is planned to study this aspect of the problem by discovering to what extent the young as well as the adults occur in the north and to make comparisons of morphological characters to see whether there are any distinguish-

ing features between northern and southern pilchards.

The second and third questions are more perplexing and their answers more remote because they involve determination of age and of abundance. Satisfactory techniques have not yet been developed for either of these determinations. Accordingly work has started on developing a technique of age determination by interpreting age marks in hard structures, by observing modal progression in sizes of young pilchards, and by identifying modes in frequency distributions of the adult population; and on developing a technique of estimating abundance from catch statistics and by aerial observation of schools, or by a combination of the two methods.

Progress in the solution of these problems will be accelerated by cooperation with State fishery research units which have collected and kindly made available many pertinent data. A series of measurements based on samples collected from the commercial catch over a period of years by the California State Fisheries Laboratory is

expected to be particularly useful in this connection.

Although the discovery of techniques of age and abundance determinations are prime essentials and will greatly advance the understanding of conservation problems, it must be pointed out that preservation of an adequate spawning reserve will require a quantitative determination of annual egg production in all potential spawning areas. This cannot be undertaken until a seagoing vessel is available to make periodic surveys in cooperation with such boats as the States have available for this purpose.

#### GREAT LAKES FISHERY INVESTIGATIONS

Dr. John Van Oosten, in charge

The limited amount of field work conducted during 1937, permitted the Great Lakes staff to continue the compilation of extensive data collected in earlier years. In addition to the papers published by staff members during the year, several other manuscripts were prepared for publication. Among these was a report setting forth the results of an intensive study of the whitefish fishery of Lakes Huron and Michigan. This investigation was concerned es-

pecially with the effects of the deep trap net fishery on the abundance

of whitefish in these two lakes.

Two important forward steps were made in Great Lakes fisheries administration during 1937. First, the adoption by Wisconsin, Illinois, Michigan, Ohio, and the Province of Ontario of the flexible rule method of measuring gill net meshes brought a troublesome problem to a satisfactory conclusion. The flexible rule provides an extremely accurate and impersonal method of determining the legality of gill net meshes. Earlier methods of gauging gill net twine were open to the criticism that the results obtained varied according to the procedure followed by the individual making the measurements. The second important advance in Great Lakes fishery administration was the passage of the "discretionary power" act by the Wisconsin Legislature. This law empowers the State conservation officials, after consultation with and on the advice of commercial fishermen, to enact commercial fisheries regulations by decree. As a result the conservation officials can meet emergency situations readily and are also in position to frame a rational long-time program for the rehabilitation of Wisconson's sadly depleted fisheries.

No significant advance can be claimed in the fundamental problem of obtaining uniform regulations for Great Lakes fisheries, nor does there appear to be much likelihood that adequate and uniform regulations can ever be attained through the medium of interstate agreement. The growing realization that satisfactory fisheries regulations cannot be attained by the united action of the States is reflected in a rising sentiment for the regulation of Great Lakes

commercial fisheries by a Federal or international agency.

Active cooperation continued to mark the relationship of the Great Lakes staff with the State officials and with the fishing industry. Cooperative projects requiring field work were the gill net investigations on Lake Erie, the study of the effect of commercial fishing on the game fish in Potagannissing Bay, Lake Huron, and the general survey of the relationships between sport and commercial fishing in southern Lake Superior and northern Lakes Huron and Michigan. Dr. Van Oosten again issued numerous memoranda relative to Great Lakes fisheries problems, and on several occasions at the request of State officials aided in the framing of commercial fisheries regulations.

The Bureau is greatly indebted to the University of Michigan for laboratory space, and for numerous other accommodations and

courtesies extended to the staff.

# FISHERY STATISTICS

A complete analysis, by methods outlined in previous reports, was made of the 1936 statistics of the commercial fisheries of Great Lakes waters under the jurisdiction of the State of Michigan. There are now available detailed records of fluctuations in fishing intensity and in the production and abundance of the important commercial species over an 8-year period (1929–1936) for each of the 22 fishing areas or statistical districts into which the State of Michigan waters have been divided. The statistical data on the whitefish in Lakes Huron and Michigan proved of great value in the study of the whitefish fisheries of these lakes completed by staff members during the year.

# AGE AND GROWTH STUDIES

Lake Erie sheepshead.—An investigation of the Lake Erie sheepshead (Aplodinotus grunniens) by Dr. Van Oosten included data on growth rate, growth compensation, the age and year-class composition of the stock, the relationship of total and standard length, the length-weight relationship, and the coefficient of condition. Although one fish in its thirteenth year and another in at least its seventeenth year (this latter fish was 27.2 inches long) were found, the bulk of the collection was made up of young fish. The dominant age-group was the I-group (1926 year-class) with an average length of 8.6 inches.

Other facts brought out were: growth compensation occurs in the sheepshead; the ratio, standard length in total length, decreases with growth; the coefficient of condition increases with age but is not

correlated with growth rate.

Lake Erie yellow perch.—The investigation of the life history of the yellow perch (Perca flavescens) of Lake Erie, suspended in 1935, was resumed in August 1937, upon the return of Frank W. Jobes to the Great Lakes staff. The preparation of a manuscript dealing with the age and growth of the yellow perch in Lake Erie is now under way. The comparison of the growth of the sexes in the yellow perch reveals an unusual situation. In the first year of life the males grow more rapidly than the females, but in all later years the females have the better growth.

An integral part of the growth study is the examination of the body-scale relationship as determined from measurements of selected or "key" scales. From the preliminary tabulation of the material it appears doubtful whether any simple mathematical formula can be employed in the calculation of the growth of the Lake Erie yellow perch. The use of a purely empirical curve of the body-scale rela-

tionship may prove necessary.

The coefficient of condition was found to vary according to locality and season. Sex differences occur only in the spawning season at which time the females have distinctly the higher coefficient. The study of season variation revealed that condition is best during the

summer.

Lake Erie whitefish.—After a lapse of several years the study of the Lake Erie whitefish (Coregonus clupeaformis) has been resumed. All scales have now been read and measured, and the individual growth histories calculated. Data relative to the various phases of the life history of the Lake Erie whitefish have been compiled in tabular form preparatory to writing a report on this subject.

# FOOD OF LAKE MICHIGAN LAKE TROUT AND LAWYERS

A report on the quantitative and qualitative analysis of the contents of 4,979 lake trout (*Cristivomer namaycush*) stomachs and of 1,528 lawyer (*Lota maculosa*) stomachs was completed by Drs. Van Ooosten and H. J. Deason. The food of the trout consisted of 98 percent by volume of fish of which Cottidae and Coregonidae were the principal constituents. Cottidae were dominant in southern Lake Michigan (72 percent by volume), Coregonidae in northern Lake Michigan (51 percent), but the lake shiner (*Notropis atherinoides*) was most im-

portant in Green Bay in the spring of the year (64 percent). The lawyer food consisted of 74 percent by volume of fish and 26 percent invertebrates. Dominant items were Cottidae (76 percent by volume) in southern Lake Michigan, Coregonidae (51 percent) and Pontoporeia (37 percent) in northern Lake Michigan, and Percopsis (34 percent) and Mysis (26 percent) in Green Bay. Data were also obtained on the frequency of occurrence of the food items, variation of food with the size of the predator, depth of water, season, and locality; on the number of individual fish of each species destroyed by trout and lawyers; and on the calculated volume of food preceding digestion. The lake trout and lawyers are competitors for the same food, and are both predators of the commercially important Coregonidae. The lawyer through its consumption of invertebrates is also a food competitor of the Coregonidae.

The large number of Cottidae secured from the lake trout and lawyer stomachs made possible a report on the distribution of three species, Cottus cognatus, Cottus ricei, and Triglopsis thompsonii in Lake Michigan. The number of records previously published from Lake Michigan was surprisingly small because these species are only

rarely taken by commercial fishing gear.

# SPECIAL SURVEYS

Potagannissing Bay Investigation.—The repeated insistence by sport fishing interests that commercial fishing operations should be prohibited in the Potagannissing Bay area of northern Lake Huron in order to protect game fish led to the passage of a resolution by the Michigan State Senate requesting the Michigan Conservation Commission and a representative of the United States Bureau of Fisheries to conduct an exhaustive survey of the fishery conditions in that region. A preliminary survey was made by Dr. Van Oosten and Fred Westerman of the Michigan Conservation Department from May 28 to June 2. A program of weekly sampling was instituted and was carried on by conservation officers, to determine the species composition of commercial trap net catches and particularly to ascertain how extensively game fish, especially black bass, occur in these nets. Subsequent visits to check the progress of the investigation and to amend the program were made by Bureau representatives during the periods from July 16 to 21 and August 6 to 10. The investigation will be continued throughout the winter season. Following an analysis of the data, recommendations for the regulation of the fisheries of the area will be formulated.

Lake Erie gill net investigation.—In August 1936, the gill net fishermen operating in the State of Ohio waters of Lake Erie secured a court injunction which restrained the Conservation Department from enforcing the law regulating the size of mesh in small-mesh nets. The fishermen held that their admittedly illegal nets were not catching more illegal fish than the 10 percent permitted by law. At the request of the Ohio Conservation Department and the Ohio Gill Netters Association an agreement was made on March 31, 1937, that provided for an investigation by the United States Bureau of Fisheries. Dr. Deason was in the field from April 7 to May 6 and from October 21 to November 6 collecting data on the relationship of the size of blue pike-perch, yellow perch, and saugers and the volume of

the catch to the size of the net mesh. The mesh sizes of the nets studied ranged from 25% to 215/16 inches. On the basis of the 1937 and earlier (1927–28) gill net studies, the Bureau will recommend a definite mesh size for gill nets used for all species commonly taken in small-meshed nets, and will recommend also an upward revision of the present legal size limits for blue pike-perch and saugers in order to provide better protection for spawning females. It is not anticipated that the recommendations will differ materially from those made by the Bureau at an earlier date.

Another phase of the gill net investigations was the experimental study of the shrinkage of gill net twine. The adoption of the flexible steel rule, developed by the National Bureau of Standards, and the further legal provision that net mesh must measure full size at all times, whether new or old, wet or dry, caused considerable controversy over the allowance which should be made for shrinkage in ordering new netting. At the request of the fishermen, who provided the necessary materials, experiments are being conducted to determine the maximum shrinkage, rate of shrinkage, and the relative importance of water and of several preservatives in inducing shrinkage.

The differences among various methods of measuring gill-net meshes (stretched measure, 1 pound strain on 1 mesh, 1 pound strain on 3 meshes, 8 ounce strain on 1 mesh, and National Bureau of Standards flexible rule) are being determined experimentally. This information will be submitted to the fishermen and conservation officials of those Great Lakes States that have recently adopted the flexible rule as the legal method for determining the size of gill nets.

# SHELLFISH INVESTIGATIONS

Dr. Paul S. Galtsoff, in charge

Oyster fishing continues to occupy a prominent position among the fishery industries of the country in spite of serious handicaps caused by the ever increasing depletion of natural oyster beds, destruction of valuable oyster bottoms by pollution, and depredations by natural enemies of the oyster. Dissemination of knowledge regarding the life history of the oyster has resulted in wider recognition of the fact that a system of oyster cultivation is necessary for maintaining the productivity of present resources.

Since success in the cultivation of oysters depends on knowledge of local conditions and good judgment in applying to them the basic principles of oyster culture, the shellfish investigations of the Bureau of Fisheries are conducted along the following lines: physiological studies, dealing primarily with the propagation and nutrition of oysters; ecological investigations, which provide answers to questions regarding the suitability of various waters to oyster culture; protection of oyster bottoms against starfish and other enemies; and investigations of the effect of trade wastes on oyster bottoms.

The first line of attack supplies the basic knowledge concerning the requirements and activities of the oyster which is essential for the practical oyster grower. Ecological observations made in 1937 in Long Island Sound and in the inshore waters of Virginia, North Carolina, Alabama, and Florida have been of great value to State authorities and private oyster organizations in transplanting seed and planting shells. Studies in the life history and distribution of the starfish disclose the inadequacy of present methods of control and demonstrate that in Long Island Sound control is an interstate problem. Experiments with the use of chemicals in the eradication of starfish are very promising and indicate that chemical control may soon be put on a practical basis. The work on pulp mill pollution provides convincing evidence of the toxicity of pulp mill effluent with the result that practical steps are being undertaken by interested parties to abate this hazard.

#### PHYSIOLOGY OF THE OYSTER

Physiological investigations on the oyster were carried out by Dr. Galtsoff and staff at the Woods Hole, Mass., laboratory. Studies were continued on sex changes in adult oysters, accumulation and storage of iron in oyster tissues, and the effect of industrial pollution on

respiration.

Sex changes.—The work on sex change was undertaken with the view of obtaining additional evidence of sex reversal in adult oysters. Methods used by previous investigators are open to criticism. The method of comparing sex ratios of oyster populations is obviously inadequate where both types of change—from male to female and from female to male—are involved. The method of examining the gonads of living mollusks through holes bored in the shell is objectionable because of the unknown effect of injury on the presumably

unstable gonad of the mollusk.

The method used in this investigation consisted in determining the sex of the oyster by inducing ovulation or ejaculation by increased temperature and chemical stimulation (Galtsoff, 1930, Proc. Nat. Acad. Sci., 16, No. 9, pp. 555–559). Of each of the 202 adult oysters tested at Woods Hole during the summer of 1936 an individual record of the spawning reaction was obtained and the discharged products were examined under a microscope. Each oyster was then measured and marked by engraving a number on its right shell. Elaborate precautions were taken to avoid any possibility of mismarking. Oysters were then transferred to Milford, Conn., where they were kept in large tidal tanks.

During the summer of 1937, the sex of these marked oysters was redetermined by the same method used in 1936. It was found that 9.7 percent of the oysters had reversed their sex. The percentage of reversals was considerably higher among females (13.1 percent) than among males (8.0 percent). The mortality during the year was only 7.04 percent, probably a normal death rate among adult oysters.

As previous observations by Dr. Galtsoff have shown, ovulation of the female is accompanied by typical rhythmical contractions of the adductor muscle and passage of eggs through the gills, while in the male ejaculation proceeds through the cloaca and does not involve specific behavior of the adductor. In the sex reversed males the physiological set-up of the organism changes with the change of sex and a typical female reaction develops. In several instances, however, the development of this reaction lagged, the newly formed female still acting as a male by discharging eggs through the cloaca and failing to develop rhythmical contractions of the adductor. Its kymograph record could easily have been mistaken for a male re-

action. A month later a typical female reaction was fully established. Another sex reversed male had a fully developed muscular reaction but the discharge of eggs continued through the cloaca, indicating a deficiency in the mechanism which forces eggs through the gills. All sex reversed females reacted as true males. From these observations the conclusion is reached that the female reaction has developed as a secondary adaptation which provides a mechanism for the dispersal of eggs through the water. The male reaction is regarded as a primary sex reaction of the ovster.

A hermaphroditic oyster found among a group of new oysters tested during the summer had an atypical reaction possessing the characteristics of both sexes. This oyster discharged both eggs and

sperm and was capable of self fertilization.

Present observations which establish a sex reversal in adult oysters occurring simultaneously in both sexes can be explained by assuming that the changes of the fundamentally bisexual gonad of Ostrea virginica are controlled by some hormonic system in which the development of one sex or another is inhibited. Whether these changes are hereditary characters which occur only in a certain group of individuals remains to be demonstrated by further observations. abnormal sex ratios have been observed in adult oysters grown on natural bottoms, understanding of the factors controlling the change of sex is of obvious practical significance to breeders and may be

valuable for the maintenance of spawning grounds.

Accumulation and storage of iron.—The possibility of increasing the iron content of oysters by keeping them in water to which iron oxide was added was demonstrated in a series of experiments conducted in the laboratory at Woods Hole and in tidal tanks at Milford. In the latter place iron was added to sea water by suspending several pounds of nails in bags. There was considerable discoloration of the water due to the presence of suspended particles of iron hydroxide, but there was no material increase in the amount of iron in solution. In several instances upon the addition of iron oxide the amount of iron in solution even decreased. The accumulation of iron in the tissues of the oyster gradually increased, however, rising during a 6-month period from about 150 mg to more than 1,000 mg of iron per kilo of dry meat. Histological analyses proved that iron oxide particles are absorbed by the blood cells of the gills and are carried away and stored in the mantle and in the anterior part of the body.

Effect of industrial pollution on respiration.—Suspecting that phenol salts may be the toxic substances of pulp mill waste which affect the oysters, a study was made of the effect of pure phenol on Using the technique developed in previous years the oxygen consumption of the oyster was measured under normal conditions and in water containing phenol in concentrations 1:20,000; 1:1,000 and 1:500. The results show no significant changes in the rate

of respiration in the presence of this substance.

#### OYSTER CULTURAL STUDIES

Prediction of spawning and setting in Long Island Sound.—The development of methods for accurately predicting the time and intensity of setting of oysters in Long Island Sound was one of the principal investigations carried out at the Milford, Conn., laboratory by Dr. V. L. Loosanoff and James B. Engle. To obtain a broader knowledge of conditions governing the survival of oysters in the Sound and its tributaries, a study of the physical and biological factors was undertaken on a much larger scale than had been carried out during previous years.

For observations on temperature, salinity, conditions of oyster gonads, presence of larvae in the water and their setting at various depths, 23 stations were established in Long Island Sound proper from a point opposite the mouth of Saugatuck River in the west to Joshua Point in the east. All these stations were visited every week

during the spawning and setting season.

Regardless of the fact that much work on the biology of the oyster has been carried on in local waters, no attempt has ever been made to conduct a systematic study of oyster setting in Long Island Sound proper. To fill this gap it was decided to determine the beginning and end of the setting period, the intensity of setting throughout this period, the intensity in relation to depth, the correlation between setting and the temperatures and salinity of water, and finally, the rate of survival of recently set oysters in different parts and in different depths of Long Island Sound. For these studies two oyster-seed producing areas located about 5 miles apart were chosen. The so-called Stratford Point area represented the natural oyster beds where little or no cultivation of oysters is carried on. Welch's Point area, on the other hand, was located in the center of cultivated grounds. In the studies of setting in each area, wire bag collectors of uniform size and containing approximately the same number of shells were used. The bags were removed from the water at semiweekly intervals and replaced by unused duplicates.

From the analysis of this year's observations as well as from the information already in the files of the station it may be concluded that the salinity of bottom water, which is subject to only slight seasonal changes throughout the year and remains virtually the same from year to year, is not a factor responsible for the success or failure of spawning and setting of oysters in the Sound. It was also noted that during the summer of 1937 spawning occurred at a temperature of less than 20.0° C. (68° F.) which had been regarded previously as the minimum temperature required to induce this act under natural conditions. The first and general spawning of oysters in the Sound took place on July 2 and 3. It was followed by a setting which was first recorded on July 17. Subsequent heavy settings in July and early August continued without interruption for 3 weeks. The last and rather light setting occurred on September 20. Examinations of spat collectors disclosed that setting took place from mean low water to a depth of 70 feet, but was heavier in shallow water. The first set in some places amounted to 10,000 spat per bushel, but mortality caused by attacks of starfish and drills ranged from 93 to 100 percent.

To assist the oyster growers of Long Island Sound in obtaining the best set, information accumulated by the laboratory staff was summarized and issued in weekly bulletins which were distributed through the cooperation of the Connecticut Shellfisheries Commission. The bulletins contained statements regarding the condition of oysters, changes in water temperature, and expected time of spawning and setting. A large number of oystermen availed themselves of the opportunity to obtain these data and used them to advantage by planting shells at the proper time and place. It is planned to continue this

practice and if possible to extend it to a larger area.

Control of starfish.—Observations on propagation and feeding of starfish in Long Island Sound were continued. The fact that starfish were responsible for the destruction of the greater part of the early oyster set in the summer of 1937 clearly demonstrates the importance of these studies for their control. It was found that starfish spawned on or about June 15 at a temperature of 15.0° C. (59° F.). Setting began on July 7–8, and continued until September 20. The heaviest setting occurred from the middle of July until the middle of August. As in the case of the oyster spat, the newly set starfish were more abundant in shallow water although setting took place at all the depths from low water mark to 70 feet.

Experiments on chemotropism of starfish were concluded in the fall of 1937. These experiments sustained the conclusions arrived at in 1936, when the largest part of the experimental work was done, that the chemical sense of starfish is poorly developed. Usually a starfish does not detect the presence of food until it comes in actual

contact with it.

It has been the general practice of oystermen to use boiling water or steam to kill starfish brought up by mops, an expensive procedure because of the large quantities of fuel used to maintain water at the boiling point. In the belief that water of much lower temperature would kill starfish, a series of experiments was undertaken to determine the minimum lethal temperature for these animals. It was found that a temperature of 50° C. (122° F.) was sufficient to kill the starfish and that the use of boiling water is therefore unnecessary.

Although it is well known that starfish do not occur in water of low salinity, the limits of tolerance for this species have not been determined with accuracy. Experiments undertaken to provide this information disclosed considerable individual variations in the ability of starfish to withstand brackish water. When subjected to a salinity of 14.00 parts per thousand some of the starfish died in 3 days while others survived 13 days. The limit of tolerance is probably around 16.00 parts per thousand, for in this dilution of sea water

some animals were kept alive 2 months.

At the request of Virginia oystermen a survey of the distribution and abundance of starfish in the lower Chesapeake Bay was made in March. The investigation revealed that starfish were confined to the area south of a line drawn from New Point Comfort to Cherrystone Island. The largest concentration was found near York Spit Light. Other areas of heavy infestation were found 3 miles southeast from Back River, 3 miles north of Little Creek, and in the vicinity of Old Plantation Light. The starfish population was not uniformly distributed, being on muddy bottoms where there was an abundant supply of small clams, *Mulinia lateralis*, upon which they were feeding. No starfish were found on oyster bottoms located in the areas of low salinity. In April, with the rise of water in the rivers emptying into the Chesapeake Bay, the starfish population withdrew toward the mouth of the Bay.

Effect of pulp mill pollution on oysters.—At Yorktown, Va., Dr. Walter A. Chipman, R. O. Smith, and L. L. Garriss were engaged in investigating the cause of the decline in oyster production in the York River. Studies of the effects of pulp mill pollution on oysters

are an important part of this investigation.

Confirming the results obtained in 1935 and 1936, observations made during this year showed that oysters in the York River below Claybank were healthy and marketable, while those above that point were extremely poor and unfit for market. The shells of the upper York River oysters are much thinner than those of the lower York River oysters and the meats are much more watery. The oysters of the Piankatank River which are studied for purposes of comparison were found to be in excellent condition. Chemical tests of the glycogen content bear out the observational data. During the year the fluctuations in the glycogen content of the three groups of oysters were as follows: Upper York River, 1.65–1.88 percent; Lower York River, 2.65–5.28 percent; Upper Piankatank River, 2.97–5.44 percent.

Remarkable improvement was found in the condition of oysters transplanted from beds in the upper York River to other localities. The shells were strengthened by deposition of lime, the meats "fat-

tened," and the green color of the meats had disappeared.

Additional samples of oysters were taken this year from various parts of the York and Piankatank Rivers and from other areas throughout the lower part of Chesapeake Bay for a study of the distribution of *Nematopsis*, a gregarine parasite known to infest oyster tissues. It was found that the parasite infestation was quite general and that oysters from many areas containing good marketable oysters were infested, indicating that the poor condition of the upper York River oysters could not be attributed solely to parasite infestation.

The hydrographical conditions of the York and Piankatank Rivers were observed regularly throughout the year following the same general program described in Progress in Biological Inquiries for 1936. Measurement of current velocities and of the tide in the upper York River was completed. Analysis of the completed data indicates that there is little nontidal current (average 0.04 knot downstream) and that the York River is primarily an estuary. It was found that the mean range of tide at West Point was 3.0 feet.

Comparative chemical analyses of the three main effluents of the pulp mill at West Point disclosed considerable difference in the amount of phenols, total solids, and biochemical oxygen demand of

the three effluents.

In view of the fact that it is impossible for the oyster to feed during the time the shell is held closed, observations were made of the hours per day that oysters remained open in various localities. The oysters kept in the river were connected to recorders and their activities under natural conditions observed. It was found that the oysters of the upper York River were not open as many hours per day as the oysters of the lower part of the river, the averages being 15.28 hours per day for the upper York and 20.81 hours per day for the lower York.

Physiological experiments consisted of studies of the effects of pulp mill effluents on the respiration and feeding of oysters. Continuous records of the pumping activity of oysters show marked reductions in the amount of water pumped in concentrations of 1 part per thousand or stronger of liquor from the diffuser building.

Studies employing the carmine cone and drop counting methods of measuring the ciliary activity of oysters showed that very dilute concentrations of the effluent from the diffuser building brought about depression in ciliary motion. In some instances concentrations as low as 1 part in 4,000 of the effluent in sea water reduced

the rate of flow after exposure of 2 to 4 hours.

Using the drop counting method additional experiments were performed at Woods Hole, Mass. Employing the oysters and sea water of this region results were obtained showing reductions in rate of pumping when diffuser building liquor was added to the water supplied to the oysters. The reductions observed were similar to those found at Yorktown with the oysters and sea water of that region. It was also found from tests at Solomons Island, Md., and Beaufort, N. C., that the reductions in rate of flow of water through the oysters caused by the addition of pulp mill effluents were essentially the same as in the experiments carried on at Yorktown. These experiments were completed by the carmine cone technique.

Comparative studies of the physiological effects of the three main sewer outlets of the pulp and paper mill at West Point on oysters show that the most toxic is the effluent from the diffuser building; the next place is occupied by the paper mill effluent, while the dis-

charge of the sludge pond is least toxic.

Tests with dried and ashed effluent of the diffuser building indicate that the material causing reduction in the rate of pumping by oysters is organic, for drying at low temperature and then redissolving in water materially decreases its toxicity. It was indicated by a series of experiments that aeration of the effluent for a month did not appreciably alter its toxicity. This is of particular interest since ponding of the effluent for slow oxidation is the plan of a new pulp mill being put into operation at Franklin, Va., in its endeavor to render the waste nontoxic to aquatic life.

The effects on oysters of fractions of the effluent and pure compounds known to occur in pulp mill wastes were tested to determine the active material of the effluent. Incomplete results indicate that the turpentine condensate resulting from the recovery of turpentine from the liquor is not particularly toxic to the oyster, nor was pure phenol under the experimental conditions employed. Observations on

Field and laboratory investigations have demonstrated that pulp mill effluent is toxic to oysters and that its discharge into the York River is primarily responsible for the decline of the oyster industry

phenol salts, resins, and soaps are being continued.

in this area.

Studies on the sporozoan parasite of the oyster.—Studies on the sporozoan parasite of the oyster which is very generally distributed in coastal regions from Maryland and Virginia to Louisiana were continued by Dr. H. F. Prytherch at Beaufort, N. C. Spores of this parasite were found in the tissues of the muscle, gills, and mantle, the number per oyster frequently amounting to several million. The

mature spore (length  $20\mu$  diameter  $11\mu$ ) contains a single vermiform sporozoite folded twice on itself and is the resting or final

developmental stage in the oyster.

Under natural and laboratory conditions the hatching of the spores takes place in the intestine of the common mud crabs, *Panopeus herbsti* and *Eurypanopeus depressus* after these hosts have fed on infected oyster meats. After undergoing a cycle of development in the crustacean host, the parasite reaches an infective or gymnospore stage, which is released into the water and may be carried within

the shell of the oyster by the feeding current.

Experiments with vitally stained gymnospores show that they attach to and penetrate the epithelium of the oyster gill by means of a pseudopod projected from the central cell. Later stages may be picked up by phagocytes and transported in the circulatory system to nearly all parts of the body. With the formation of heavy, double-walled sporocysts, the parasite has reached the characteristic resting or dissemination stage commonly found in *Ostrea virginica* and various other members of the same class of mollusks. Further details of the life history of this sporozoan will be published shortly in a

scientific journal.

Studies of the effect of the parasite on adult oysters were conducted in the laboratory where heavy infections could be produced. In bulk experiments with several hundred oysters, losses of 66 to 73 percent resulted over a period of 3 months. Kymograph records of shell movement of heavily infected oysters showed abnormal and frequent contractions of the adductor muscle followed by loss of holding power and death of the mollusks. The injury to the oyster host may be due to a toxin given off by the developing sporozoites, particularly in the sensitive mantle tissue, or to actual physical obstruction of the circulation by the masses of enlarged, infected phagocytes found in the blood vessels of the gills and muscle.

Practical prevention of the infection of oysters by this parasite is possible by control of the primary hosts, the mud crabs. The crabs do not migrate and can easily be removed, before the beds are planted, by the use of dredges or scrapes equipped with fine mesh bags. The possibility of destroying the crabs by chemicals such as copper salts,

chlorines, etc., is at present under investigation.

Investigations in Florida.—An experimental study of spawning and setting of oysters in Apalachicola Bay, Fla., was begun early in the spring by Dr. A. E. Hopkins. Because of the warm winter many oysters retained fully matured eggs or sperms in the gonads. Of samples taken early in March from St. Vincent Sound and Indian Lagoon, about half were mature. In the eastern portion of the bay, where the most extensive natural bars are located, only an occasional sexually mature individual was found. A month later, in early April, almost all specimens contained mature sex products. However, there was no indication of spawning until the end of April and the first of May, although for sometime previously the water temperature had been in general above 20° C. Spawning did not occur throughout the entire population at once but apparently involved only a small number of individuals at a time. A scattered set of seeds was obtained on bags of shells beginning at the end of May and continuing throughout the summer.

Tests were begun to determine the amount of meat present in oysters from different grounds with reference to the inside volume of the shells. The relative size of the shell cavity varies widely in oysters on different grounds. The volume of the shell cavity in 100×volume of cavity relation to total volume is expressed as

Total volume refers to the displacement of the entire ovster with

Total volume

shells intact but free from adhering organisms.

Each natural reef appears to be distinctive in the type of oysters produced. For some of the reefs in Applachicola Bay values ranging from 30.82 percent to 41.83 percent were obtained. (Japanese oysters grown in the State of Washington average 52.61 percent inside cavity.) The volume of the cavity of the shell constitutes a limit to which the meats may develop, but it is important to note that the best meats do not necessarily come from the shells with the largest proportion of cavity.

Ovster meats were dried at 100° C., and the dry weight determined with reference to the volume of the shell cavities in which

they lived. The following values, expressed as

# 100 x dry wt. in grams Volume of cavity in c. c.

represent the average of 20 to 25 specimens from each ground early in March before spawning had begun: St. Vincent Sound (transplants), 9.048; Indian Lagoon, 11.080; Cat Point, 4.337; Porters Bar, 10.863; Picoline Bar, 9.359; Platform Bar, 5.009; St. Vincent Bar, 4.666; Peanut Patch Bar, 3.745. Oysters from East St. Andrews Bay averaged 6.125 while Japanese oysters from Washington State averaged 11.732. Analyses of this type are being continued in conjunction with observations on hydrographical factors such as temperature, salinity, and pH of the water, abundance of plankton, degree of development of gonads, and spawning, in order to determine the conditions under which the best quality meats may be produced.

On account of unfavorable variations in salinity and turbidity of the sea water at the temporary laboratory at Indian Pass, near Apalachicola, Fla., headquarters for investigations were moved to the Pensacola Bay region. The Pensacola Quarantine Station of the Public Health Service was transferred to the Bureau of Fisheries for use as a laboratory. The main building has been equipped with running sea water and other necessities. The location is most favorable for oyster investigations, being within a short distance of the extensive oyster grounds of Florida, Alabama, Mississippi, and Louisiana, and having a supply of clear, clean sea water for

laboratory investigations.

#### SPECIAL SURVEYS

Effect of dredging operations in Buzzards Bay.—At the request of the U.S. Engineer's Office, a special survey of oyster beds in Buzzards Bay was made by Dr. Loosanoff with the view of determining the condition of oysters and bottoms in the vicinity of the dredging operations performed by the War Department at the entrance to the Cape Cod Canal. Detailed information was supplied to

the Engineer's Office as a result of this survey.

Survey of oyster bottoms in Shinnecock Bay, Long Island.—At the request of C. E. Dimon, secretary of the Board of Trustees of the town of Southampton, Long Island, N. Y., Dr. Loosanoff was detailed to study the conditions responsible for the disappearance of

oysters.

It appears from the two surveys carried out in July and October in Shinnecock Bay, that the largest part of this once productive public oyster bottom is at present either much depleted or entirely barren. Studies of conditions existing in the bay failed to establish valid reasons why oysters could not be cultivated in that bedy of water. The presence of a large number of marine animals of various types ranging from the lowest invertebrates to fishes, and including many species closely related to oysters, also indicates that physical and chemical conditions in the bay are basically favorable. It seems, however, that the exceedingly dense growth of sea grass and hydroids on the bottom of the bay may be partly responsible for the lack of oysters in many parts of that body of water. Such a heavy growth covering the bottom undoubtedly prevents the setting of oyster larvae, and interferes with the circulation of water, thus depriving oysters of their food. It is probably significant that at the only station in the bay where oysters were found, little or no grass was brought up in dredges. A heavy growth of hydroids at that station was probably responsible for the poor growth of oysters. The abundance of starfish and drills is considered another factor responsible for the disappearance of oysters from the bay.

According to the town's regulations the oyster bottom of Shinnecock Bay is public property, no private ownership of the oyster grounds being permitted. Because of the almost complete disappearance of oysters, however, members of the community derive little benefit from the resource. The present regulations are therefore of sentimental rather than of practical value. The very fact that the oyster grounds are public property may be responsible for the disappearance of oysters. Oystermen who make their living from public beds take, as a rule, very little care of them. No regular shell planting is practiced, and no attempts are made to combat oyster enemies such as starfish and drills. As a result, these oyster bottoms which have been very prolific in past years are either entirely barren or show a marked decrease in yield. Because of lack of cultivation, oyster grounds are being gradually covered with debris and a dense growth of sea grass and hydroids, which make them unsuitable for oyster growing.

Considering the facts that Shinnecock Bay is at present virtually devoid of oysters and that the Board of Trustees has no funds to engage in oyster cultivation it is recommended that the bottom of the bay be leased to persons depending upon shellfisheries for a livelihood so that planting, cultivation, and protection of oysters may be

resumed.

Pollution of water in Cherrystone Inlet, Va.—Upon the request of the Virginia Commission of Fisheries, investigations were carried out by Dr. Chipman to determine the cause of the high mortality of crabs and fish in Cherrystone Inlet last summer. It was found that the waters in question were polluted by cannery wastes. Determinations of the dissolved oxygen content and oxygen capacity of the water demonstrated the presence of a considerable amount of unstable organic matter in the water in the vicinity of the ditch leading from the cannery and extending into Cherrystone Inlet. From a 24-hour period of observation of the dissolved oxygen content of the water it was found that the dissolved oxygen in the early morning hours reached the extremely low level of only a few tenths of a part per million. Photosynthesis during the day brought about supersaturation of the water with oxygen in the late afternoon. The low oxygen area extended only a short distance into Cherrystone Inlet. On the basis of observations obtained from several trips to the area it was concluded that the high mortality of crabs and fish was a result of insufficient dissolved oxygen in the water, a condition brought about by the emptying of organic matter with high oxygen demand into the inlet by the cannery.

Investigations of the periodicity of fouling organisms.—At the request of the Bureau of Construction and Repairs, U. S. Navy Department, an analysis of the fouling organisms grown on experimental panels exposed at Cavite, Philippine Islands, and Guantanamo Bay, Cuba, was undertaken under the direction of Dr. Galtsoff. The work consisted in identifying the principal fouling groups and determining their abundance and the sequence of their appearance. The work was begun in September at the U. S. Fisheries Laboratory at Woods Hole and is being continued now by G. Robert Lunz, Jr., at the

Charleston Museum, Charleston, S. C.

# AQUICULTURAL INVESTIGATIONS

Dr. H. S. Davis, in charge

It is now generally conceded that proper and efficient utilization of the fish resources of our inland waters is to be achieved only through the adoption of a comprehensive plan of fish management adapted to the needs of each body of water. The rapid increase in the number of anglers coupled with the construction of thousands of miles of new highways has resulted in such a drain on the fish population that previous methods of more or less haphazard stock-

ing have proved inadequate to cope with the situation.

The need for the development of management plans has served to focus attention on the lack of factual information on which such plans must be based. Although the artificial propagation and rearing of trout have been practiced on an ever increasing scale for many years, there is little information on the survival of hatchery fish after being liberated in natural waters. There can be no question that stocking with legal trout shortly before and during the open season has been a success. There are also a few instances where stocking with smaller fish is known to have resulted in a material improvement in fishing. In the great majority of cases, however, there is no evidence that artificial stocking has had a beneficial effect. On the other hand there is considerable evidence that, in many cases at least, stocking has had very little effect on the fish population and that even in heavily stocked waters wild trout frequently make up the bulk of the catch.

Although it is probable that artificial stocking has been more successful than is indicated by available information, the conclusion is inescapable that a large percentage of hatchery fish have been wasted and that the only hope for improvement lies in acquiring information that will enable us to avoid the pitfalls of the past. It is a striking commentary on fish management as practiced in this country that while hatchery operations and methods of transporting fish have been materially improved in recent years, the fate of the fish after stocking has received practically no attention. We are confronted with an anomalous situation in which a highly organized industry producing an extremely perishable product at great labor and expense is almost entirely oblivious to the fate of that product once it leaves the hatchery. Both fish culturists and anglers call for fish, and still more fish, without any attempt to determine whether increased production is the answer to the almost universal complaint that fishing is growing poorer each year.

In view of these facts, a large part of the activities of the aquicultural staff is devoted to acquiring information on the results of stocking and the survival and growth in natural waters of hatchery fish as compared with wild fish. In addition to field studies, investigations of hatchery problems have been continued and arrangements have been made to devote more attention to such problems in the

future.

# TROUT

Test streams.—The scientific work at the Pittsford (Vt.) station under the direction of R. F. Lord has centered around the "test waters" which are managed in cooperation with the State Fish and Game Service. During the past 2 years three streams and one lake—the maximum authorized by law—have been operated as test waters. Of these streams only Furnace Brook has been operated as a test stream for 3 consecutive years. The total catch of legal trout in this stream was 8.589 in 1935, 6.995 in 1936, and 6.385 in 1937. It is evident that in spite of heavy stocking the yearly catch is gradually decreasing, as is the average catch per fishing effort, which dropped from 7.2 trout in 1935 to 6.5 trout in 1937. On the other hand it is surprising to find, as pointed out in previous reports, that there has been only a slight decrease in the catch of rainbow trout, which have not been planted in the streams in recent years and are, consequently, entirely dependent on natural propagation. As a result of the much greater decrease in the catch of brook trout the proportion of rainbows in the total catch rose from 34 percent in 1935 to 38 percent in 1937.

During the past season a field census station was operated on Furnace Brook every week end to obtain accurate information on the marked trout taken by anglers. These fish were over 6 inches long when planted as yearlings in the fall of 1936. Although only 7 percent of the marked fish planted were reported by anglers, a creel check showed that approximately 50 percent of the marked fish taken were overlooked. This would indicate that of 5,200 legal fish planted in Furnace Brook during the fall of 1936 only about 14 percent appeared in the anglers' catches the following season.

There is, as yet, no information on the fate of the remaining 86 percent.

On an acreage basis it is estimated that the total production of trout in Furnace Brook was 45.55 pounds per acre in 1935, 37.45

pounds per acre in 1936, and 37.17 pounds per acre in 1937.

It is interesting and most encouraging from a fish management standpoint to find that, although the number of anglers was much greater early in the season than later, there was very close agreement throughout the season between the percentage of angling effort and the percentage of fish taken. In other words, the average catch per fishing effort was remarkably constant throughout the season. This provides strong support for the view that where conditions are favorable for trout it should be possible to maintain good fishing up to the end of the season, even in heavily fished waters.

Growth and food studies on St. Mary's River.—St. Mary's River, a trout stream near Vesuvius, Va., in the George Washington National Forest, was stocked with marked brook trout above the falls (impassable) and with marked rainbow trout below the falls in 1935 and 1936. Owing to the poor growth of the fish, the stream was not opened to fishing in 1937 and thus afforded an opportunity for a study of the trout population by E. W. Surber and Dr. J. S. Gutsell. The fish were caught almost exclusively by angling and most of them

were returned to the stream after examination.

It was found that brook trout planted in 1935 had grown to an average length of 5.6 inches in April, 6.2 inches in July, and 6.6 inches in November. Only a few rainbows planted in 1935 were caught but the 1936 planting was well represented. These fish averaged 6 inches long in April, 6.8 inches in July, and 7 inches in

November.

An examination of the stomach contents of brook and rainbow trout caught in May 1936 showed that the number of terrestrial insects greatly exceeded that of aquatic forms. Of special interest was the evident importance of crayfish as a trout food and the presence of considerable quantities of algae in the stomachs of rainbow trout. Parasitic nematodes were found in nearly all stomachs of both species of trout. These worms were present in considerable numbers and may be responsible, in part at least, for the slow growth of trout in this stream.

Pisgah Forest project.—The experimental fish management project in the Pisgah National Forest (N. C.) has now been in operation for over a year in cooperation with the U. S. Forest Service. The project is under the supervision of Wm. M. Keil, of the Forest Service, while the biological work is being conducted by Thomas K. Chamberlain, of

the Bureau of Fisheries staff.

A detailed survey of the streams under management has been completed and maps prepared showing the physical characteristics of

stream channels and banks.

Collections of bottom samples at 51 stations have been regularly and systematically carried out. Five of the major watersheds of the forest are included in these studies, although most attention has been given to the Davidson River drainage, where monthly collections are made from 51 square feet of bottom. Although still far from complete for the purpose of calculating the maximum carrying capacities of

the various streams, the results were used as criteria for setting up

the initial stocking program.

Other investigations in this area include studies of the food of trout and other fish, collections of scales from brook, rainbow, and brown trout to be used in a comprehensive study of the growth of both wild and hatchery-reared trout in natural waters, and studies of the survival of trout after planting and their adjustment to the new environment, with special attention to the effect of winter conditions.

The Davidson River rearing station, constructed by the Forest Service, was operated very successfully. Sufficient trout of various ages and species were produced to carry out the stocking program as originally planned. Most of the fish were planted at 9 months of age and were as large as the average wild fish in their second and third years. While this growth rate cannot be expected to continue, these fish have at least been started in their new surroundings with strong, healthy bodies and a year's advantage in size. Specimens examined 2 to 3 months after planting were in excellent condition and compared favorably with wild fish in the same stream.

The Pisgah National Forest affords exceptional opportunities for fish management studies, since all streams can be opened or closed to fishing whenever desired and a complete check can be made of anglers' catches. The streams are patrolled regularly by Federal game ward-

ens and there is little poaching.

Climatic and water conditions are also exceptionally favorable for management studies. The district has one of the heaviest rainfalls in the United States and participation is normally regular throughout the year. The comparatively short, mild winters allow a long growing season for fish and opportunities for studies of fish and fish food organisms that are not possible in more northern sections. Among the problems that are under investigation in this area is the extent to which both brook and rainbow trout of various ages and sizes migrate downstream when planted in the smaller and higher tributaries. The results of these studies will have an important bearing on the advisability of establishing so-called nursery streams that are closed to fishing on the assumption that the trout on reaching a certain size will descend to larger waters where they will be an important factor in maintaining the supply of legal trout.

Experiments are also under way to determine the stocking intensities of trout of various sizes that will produce most satisfactory results and the effect of various types of stream improvement on the production of fish and bottom food organisms. In several streams only marked trout of uniform size were planted so that it will be possible

to get reliable data on the growth and survival of these fish.

California trout investigations.—The investigational program of this unit was continued under the direction of Dr. P. R. Needham, and good progress has resulted in spite of several changes in personnel and program. A. C. Taft resigned from the position of assistant aquatic biologist in January 1937, to become Chief of the Bureau of Fish Conservation of the California Division of Fish and Game. This position was not filled for the remainder of the fiscal year. As a consequence, the coastal stream steelhead investigations were turned over to the State Division of Fish and Game to be continued under the direction of that agency. Investigations at

the Hot Creek Rearing Ponds Project were concluded June 30, and investigations on the survival rates of hatchery-planted trout by means of the Convict Creek experimental stream, operated in cooperation with the U. S. Forest Service, were substituted as a major

project.

Twenty-three plants of brook, brown, and rainbow trout were made during the season of 1937 in the experimental stream. Various age groups were used, and plantings were made under varying predator conditions to determine survival rates over varying intervals of time. Several of the experiments were failures because of faults in the physical set-up, such as holes under dams and clogging of screens. The information obtained during this first year has pointed the way for future operations and the biological data have provided definite guides for stocking programs. the successful experiments it was determined that hatchery-reared advanced fry suffer great losses in wild waters, but that hatchery fish from three to four inches long show a high survival. trout did better than the other species with rainbow trout next in order of success in the experimental plants. Studies of condition factors showed that hatchery-reared fish lost weight after planting and a measure was determined for the optimum stocking intensity in relation to the food supply.

In one section a survival of 100 percent was obtained following a plant of rainbow trout based on the table developed by Dr. G. C. Embody. In another section, stocked with 1,000 advanced cutthroat fry, only 34 fish survived to the end of the season. The presence of 10 wild predatory trout was responsible for the heavy

losses.

In future operation it is planned to divide the experimental stream into a smaller number of sections. Emphasis will be placed

on planting experiments with rainbow and brown trout.

Boat catch records were again obtained from anglers fishing Convict Lake. The catch per unit of effort rose slightly from 0.21 fish per hour in 1935 to 0.27 fish per hour in 1936. A total of 365 trout were reported by 286 anglers in the 1936 season while 184

anglers took only 167 trout in 1935.

Of the trout caught in Convict Lake in 1936, over 49 percent were unmarked rainbows and approximately 48 percent were brown trout. Only seven marked rainbows from the plant of 2,014 (average length 5.67 inches) planted in July 1935, were reported caught by boat fishermen in 1936, while 349 of these fish were caught in the season of 1935. Therefore, in 2 seasons' fishing a total of only 356 trout, or approximately 18 percent, of the 2.014 planted in 1935 have been reported caught. However, such a low survival may prove to be more apparent than real, since fish planted in the lake can easily leave through either the inlet or outlet. Several reports were obtained of marked rainbow being caught as much as one-half mile below the lake.

Cooperative investigations with the U. S. Forest Service were continued in the national forests of California, Oregon, and Washington. A survey was completed and stocking policies were developed for the headwaters of the South Umpqua River above Tiller, Oreg., in the Umpqua National Forest. In addition, complete angling catch records were taken on Fish Lake by the Forest Service. Fish Lake,

with an area of approximately 90 acres, lies at the very head of the Umpqua drainage. A total of 5,946 trout were reported caught, of which 5,878 were rainbow and the rest, eastern brook trout. The catch per angling hour was 4.18 fish. The total catch weighed 1,821 pounds which is a production of approximately 20 pounds of trout per acre of water area. The average length of the fish taken was about 9½ inches with an average weight of approximately 5 ounces. In 1935 and 1936 a total of 40,000 eastern brook trout were planted in Fish Lake, yet as noted above only 68 of this species were reported caught.

Through cooperative work in the Willamette National Forest in Oregon, a total of 174 lakes have been surveyed in the last 2 years

and stocking policies recommended.

The U. S. Forest Service also financed the collection of catch records on Squaw Creek, a tributary of the Pit River in the Shasta National Forest. While no records were obtained for the month of May it is estimated that they are about 98 percent complete for the remainder of the season. A total of 2,497 rainbow and 7 brown trout were reported taken. The average catch was 7.4 fish per angler. Of rainbow trout taken, the 6- to 8-inch group formed 48.70 of the total and the 4- to 6-inch group 29.75 percent. Fish over 10 inches long made up only 5.3 percent of the rainbows caught. It is interesting to note that in the 4-year period from 1933 to 1936, 140,000 brown trout were planted in Squaw Creek. The fact that only 7 trout of this species showed up in the catch is strong evidence that conditions in Squaw Creek are not suited to brown trout and that the fish planted in this stream were wasted.

Introduction of Mexican trout.—In May 1937, Dr. P. R. Needham, accompanied by Fred Johnson of the U. S. Forest Service, made a trip to the Santo Domingo River in Baja California, Mexico, to secure living specimens of the southernmost coastal rainbow trout, Salmo nelsoni. The effort was highly successful and 50 fish were transported to the State hatchery at Forest Home in Southern California. These fish are to form the nucleus of a hatchery brood stock of this strain of trout. Efforts along this line are considered well worthwhile since it is hoped that these fish may be adapted to warmer water than other species of trout and that they also may prove to be nonmigratory. As soon as sufficient numbers are obtained, both laboratory and field experiments will be conducted to determine their true character and range of adaptability to varying stream conditions.

Nutrition studies.—Studies on trout nutrition have been continued at Cortland, N. Y., by Dr. C. M. McCay and A. V. Tunison. Two methods of attack upon the problems have been employed. The first attempts to improve current practices by the introduction of new feedstuffs that are available in large quantities and by improving the quality of the mixtures in current use. The second attempts to secure fundamental data in the fields of biochemistry, growth, and physiology in the interest of providing a sound basis of true science for guiding our changing practices. The study of disease at the Cortland Hatchery has been of minor importance since this involves special techniques that are not available. However, some attention has been given to diseases as they have arisen from time to time in the course of the other studies.

A better knowledge of the phenomena of growth whether of the entire body of the fish or of the component parts and their composition, is essential for a science of fish culture. For this reason four species of trout-rainbow, brook, lake and brown-have been under constant observation for 5 years. These four groups have been fed the same diet and kept under similar conditions in regard to the water supply. Growth curves for the four species under these conditions have been very similar. Increases in body weight have continued throughout this period but this growth rate has declined with succeeding years. This indicates that growth is determinate in fish although the cessation of increase in the size of the body is in a much later period of the life span than it is in higher mammals.

In the course of this long-time experiment certain species differences have been observed. All except the lake trout spawned at a normal age but this species did not spawn until September of 1937 when nearly 5 years of age. As the groups have become older there has been a tendency to develop ulcer disease and for individuals to die at about the spawning period in all groups except the lake trout. All of the brook trout have now died. The males of this group died before the females. The eggs from all groups have been consistently inferior and smaller than those from the same species held in ponds.

The question of the rate at which an animal should grow in order to develop the strongest body possible is one that is attracting increasing consideration in many fields of animal nutrition. desires to push the growth of an animal to the extent that he produces weaklings. One of the most difficult problems in the field is to determine what constitutes a weak animal in terms of the organs of the body and to detect weak organs that are unable to share in the growth of the body when that growth is unduly accelerated. For the above reason studies have been made of the rates of growth of the organs of the bodies of four trout species during the fingerling

In this study the weights of the eyes, livers, hearts, and gastrointestinal tracts of trout were determined on April 16, July 9, and October 1. Part of the trout had been retarded in growth and part made to grow as rapidly as possible under our conditions. It has already been demonstrated by investigators working with other species that the organs of trout grow at unequal rates in comparison with the whole body. In cases of limited available foodstuffs certain organs, such as the eyes, are able to seize a disproportionate share compared to organs such as the heart. Thus, in retarded trout, the eyes grow more than the other organs and tend to represent a greater percent of the entire body weight. Organs such as the heart, liver, and the gastrointestinal tract represent about the same percent of the entire body weight whether the trout has been retarded in growth or not. In last analysis these organs and their composition probably determine whether or not the trout that are planted in the streams survive to greet the fisherman or die from their own inherent weaknesses. The tendency of the eyes to become a larger percent of the entire body weight may ultimately prove of some use as additional measurements of "condition factors."

As an additional part of the program to extend the science and to determine more about the relative hardiness of trout that are produced in hatcheries, the Cortland Station has continued its study

of the chemical composition of trout of different ages. This work has been severely hampered by lack of both equipment and skilled assistants but progress is being made. As this phase of the work progresses it is hoped to include even the egg in its early development because here must lie some of the secrets of producing sound trout. Special attention is now being devoted to the exchange of nutrients between the sac and the fry in the period just after the eggs are hatched.

In the interest of improving the practical diets now used in the hatcheries special studies have been completed during the past year of such products as linseed meal, meats preserved in acid, various fish meals and seal meal. Linseed meal has been freed from its poison by steaming and pressure cooking. These processes provide a nontoxic meal that still retains the important property of

binding water and liquids such as meat juices.

In the study of preserved meats it has been found that acids such as hydrochloric, phosphoric, and acetic, are satisfactory especially when their action is supplemented by that of molasses. After long storage of ground meats and molasses the meat tends to liquefy and to lose some of its value probably due to the loss of factor H. No evidence of toxicity has been discovered and the hydrolysis is only partial because there is little increase in amino nitrogen. A satisfactory method of keeping meats for long periods without spoilage, without deterioration in nutritive value and without loss of physical properties, has not been discovered thus far but progress is being made. The importance of such a development is evident since it would decrease the labor and the investment in refrigeration equipment as well as make it possible to purchase meat at periods of low prices.

Salmon carcass meal has proved somewhat more satisfactory in practical feeding than seal carcass meal although both can be used. White fish meal from which much of the bone has been excluded has been found of sufficient value to justify the additional cost of this

special product.

The primary function of the Cortland station has been to develop a science of fish nutrition and to provide improved feeding practices for American hatcheries. Inevitably, however, diseases other than nutritional ones arise in the course of such investigations. These have been excluded when possible but some use has usually been made of epidemics to discover possible interrelationships with the nutrition.

During the spring of 1937, the yearling and adult brook trout developed ulcer disease. These were divided into groups and fed various vitamin concentrates and specific chemical compounds. Some of the products fed were vitamin C, extract of pine needles, potassium iodide, dried yeast, arsenious oxide, boric acid, borax, dinitrophenol, thallium acetate, and sulfanilamide. This heterogeneous list represents specific selections in a rational attack but failure resulted in every case. The last compound, sulfanilamide, was the only one that afforded any hope of usefulness that would justify further study.

During the past year efforts have been continued to develop better methods for chemical balance studies with trout. The aim of such studies is to measure the fractions of foods that are utilized after they are ingested by trout. In this work as in all projects involving chemical techniques, progress has been slow owing to the difficulties of the problem and to the deficiency in equipment and trained

personnel.

At the Leetown, W. Va., station, an experiment was conducted with rainbow fingerlings, to test the value of certain commercial feeds in comparison with seal meal and salmon carcass meal manufactured by the Bureau. The dry foods were first fed at a 30 percent and later at a 40 percent level with beef liver. The fish fed salmon carcass meal rapidly outgrew those on other diets and at the end of the experiment were 42.4 percent heavier than those in the best of the other lots.

Selective breeding.—Selected lots of fingerlings were carried through the summer of 1937 at the Pittsford station and the best lots retained for breeding purposes. In the fall of 1937, 50 pairs of the best available 2-year fish were mated and the eggs segregated.

Owing to the necessity for economy in operation of the hatchery, it has not been possible to obtain maximum growth in the select lots but the effects of breeding are nevertheless manifest in the yield of eggs which averaged 1,370 per pound of fish instead of the usual rate of 1,000 eggs per pound for fish of the same size.

#### BASS

The field studies on smallmouth bass begun in 1936 were continued under the direction of E. W. Surber. These investigations are concerned with much the same problems in bass streams as are the trout studies in colder waters. Although, as already pointed out, there is a surprising lack of factual information necessary for the formulation of fish management plans for trout waters, the dearth of information concerning bass waters is even more marked. systematic studies on the activities of bass in natural waters have been feasible throughout the year and there is practically no information on the normal productivity of bass waters. Although bass are now being propagated on an extensive scale throughout the country there is little evidence that fishing for either large or smallmouth bass has been appreciably improved by stocking. It is probable that natural propagation is more efficient than in the case of trout and that there may be less need for artificial aid. This, however, is a matter that can be determined only by comprehensive and systematic studies carried on continuously over a considerable period. It is for the purpose of securing such basic information that the investigations on bass streams were inaugurated and the results already obtained are of great practical value.

In addition to the two experimental sections previously established on the Shenandoah River near Berryville, Va., and on the South Branch of the Potomac River near Romney, W. Va., observations were made on sections of similar length in the Cacapon River near Largent, W. Va., and the North Fork of the Shenandoah River near Strasburg, Va. Stream conditions were entirely satisfactory for observations on the extent of natural propagation in the South Branch and Cacapon Rivers but in the Shenandoah and its North

Fork visibility was much poorer.

Observations on spawning.—In the 1937 survey of the 3-mile section of the South Branch 205 smallmouth nests (68.5 per mile) were found on May 14 and 15, as compared with 142 nests found in this section during the 1936 survey. These nests were at an average depth of 33.2 inches and the average distance from shore was 9 feet. The eggs were counted in 10 nests and found to average 1,700 to each nest. Very few dead eggs were found.

In the Cacapon River, the average number of nests per mile was 13.75 and in the Shenandoah River there was an average of five nests per mile. Owing to the turbidity it is probable that some nests escaped observation. Fry counts made later along the same section indicated that the number of nests must have been considerably greater than observed. On the North Fork of the Shenandoah River an average of five nests per mile were observed in the experimental

section.

In spite of these unfavorable conditions, a considerable number of older bass were taken for scale studies. In the South Branch of the Potomac River the average length of bass in their second year was 6.69 inches, in their third year 8.75 inches, in their fourth year 10.13 inches, in their fifth year 10.81 inches, in their sixth year 16.0 inches, and in their seventh year 17.0 inches. In other words, small-mouth bass in the South Branch did not attain the legal length of 10 inches until their fourth year and of the fish of this age more than 42 percent were under legal size.

In the Cacapon River the meager data available indicate that the situation is even less favorable. Of 24 smallmouth bass taken by angling on June 1, not a single fish was of legal size and the largest fish taken (9.75 inches) was in its fifth year. A 6-year fish was only

9.5 inches long.

On the other hand, bass in the North Fork of the Shenandoah River were found to make much more rapid growth. Here 2-year fish averaged 7.69 inches in length, 3-year fish 10.52 inches, and fish taken in their fourth year showed an average length of 12.13 inches. It is interesting to note that the North Fork is very nearly the size of the South Branch.

During 1937, progress was made toward placing field observations on a quantitative basis. Counts of bass in three sections of the South Branch of the Potomac River varying in length from 3 to 4.6 miles agreed very closely, showing, respectively, 105, 107, and 124 fish per mile. In contrast only 19 bass per mile were noted in the North

Fork of the Shenandoah River.

It is of interest to note that in these rivers all of the bass appear to spawn at one time and there is no evidence of later spawning extending into the month of June. In the South Branch of the Potomac, where the extent of natural spawning is greatest, the fry disappear with extreme rapidity and there seems little doubt that the

bass themselves are largely responsible for the losses.

Growth studies.—Fingerling bass in the South Branch of the Potomac attained an average length of 64 mm by mid-September while the trend in the growth of fingerlings in the Shenandoah River (no collections made after July 30) indicated that the bass in this stream again would have easily outstripped those from the South Branch had they maintained the growth rate shown by fish collected up to July 30, when the average length was 59.5 mm. In the Cacapon

River fingerling bass averaged 69 mm in length by September 1, and in the North Fork of the Shenandoah the average length on September 16, was 75 mm.

The 1937 season proved a poor one for the collection of fish and bottom organisms because of high water from frequent rains. As a result samples could not always be collected at regular intervals, and

the number of fish caught was sometimes inadequate.

There seems little doubt from general observation that forage minnows are considerably more abundant in the Shenandoah River and its North Fork than in the South Branch and Cacapon Rivers, but to date the quantitative methods employed have not established this fact.

One of the most important results of the studies on the Shenandoah and South Branch of the Potomac Rivers during the past 2 years is the evidence that the latter stream is at present overstocked with bass. That this is the case is indicated by the large number of bass nests observed and the slow growth of young bass in the South Branch. In this stream smallmouth bass do not attain the legal length of 10 inches until their fourth year and over 42 percent do not reach this size until their fifth year. In contrast, bass in the North Fork of the Shenandoah, which is comparable in size with the South Branch, reach legal length in their third year and in their fourth year average two inches longer than bass of the same age in the South Branch.

The large number of nests observed in the South Branch also leads to some interesting speculations on the effect of stocking. As previously stated, an average of 68.5 nests per mile were observed in 1937 in the experimental section. Since the average number of eggs in each nest was approximately 1,700 and there were very few dead eggs it is evident that at least 115,000 fry per mile were produced. It is not probable that all the nests were seen, since observations were made only on two consecutive days, so that we may estimate the fry produced in this section of the river at over 125,000 per mile. There are approximately 75 miles of bass water in the South Branch and if we assume that an average of 100,000 fry per mile were produced in this area we find that it would require 7,500,000 fry to stock the South Branch at the same rate as was done by nature. Even if we reduce the estimate by 50 percent some 3,750,000 fry would be required, which would be a large order for any hatchery.

Food studies on fingerling smallmouth bass.—The stomach contents of 1,076 fingerlings collected at monthly intervals in test sections of the South Branch and Shenandoah Rivers have been examined. These collections permitted seasonal comparisons of the food of growing fingerlings from the time they rose from the nests until the end of the growing season. It was surprising to find that 10 percent of the Shenandoah River fry, averaging 10 mm long, had consumed fish. Many of these bass had not yet completely absorbed their yolk material. The chief items of food, however, were nymphs of the genus Boetis and midge larvae. As the bass increased in size, fish became more important in the diet, except in the South Branch

where the data reflect a scarcity of forage minnows.

Bottom fauna studies.—A quantitative study of the bottom fauna in the Shenandoah and South Branch Rivers showed that the number and weight of organisms per square foot was much less in the pools

than in the riffles in both streams, but in pools of the South Branch there was about twice as much food as in pools of the Shenandoah The weight of organisms per square foot in the riffles was considerably greater in the Shenandoah than in the South Branch. Moreover, the former river has more extensive riffles in which bass can feed than has the latter.

Parasites in fingerling bass.—It was found that fingerling bass from both the South Branch and Shenandoah Rivers were infested with parasitic trematodes that were encysted in the liver. These parasites were much more numerous in fish from the South Branch than in those from the Shenandoah. Approximately 75 percent of fingerling bass from the former stream were parasitized as compared with about 12 percent from the latter. Bass from the South Branch also contained many more cysts, on the average, than those from the Shenandoah River. Considering the abundance of cysts in many instances, it is remarkable that there is no evidence that the parasites affected the growth since the average size of infested fish was

very nearly the same as that of the uninfested.

Forage minnows in bass ponds.—Three ponds at the Leetown Station were stocked very heavily with blackhead minnows before the bass fry were introduced. Each pond when drained in the fall contained only a relatively small number of bass, although they were all of large size, averaging 6.5 inches in length. The obvious explanation of the disappearance of the bass fry is that they were eaten by the minnows although direct observations are lacking. In view of this possibility, it seems advisable to rear bass fry to a larger size before transferring them to ponds containing forage fish, or to defer the stocking of broad minnows until the fry have attained a length of three-fourths of an inch or more.

#### FISH DISEASES

Studies on fish diseases were continued by Dr. Frederic F. Fish at the pathological laboratory in Seattle, Wash. An investigation of furunculosis completed at Lake Madison, Mont., showed that a small percentage of loch leven trout were infected with the disease. Spawntakers, however, reported the incidence of infected fish to be much lower than in 1934 and 1935. They also reported that the number of fish running into the traps showed a marked progressive decline during those years. It appears probable that furunculosis contributed materially to this decrease in the loch leven trout population in Lake Madison. If this supposition is correct cyclic increases and decreases in the numbers of these fish are to be expected in the future.

A program of disease control studies was instituted at the field laboratory recently constructed with the cooperation and financial assistance of the Division of Fish Culture at the Bureau's hatchery located at Quilcene, Wash. Both preventive and therapeutic measures for combatting the common hatchery diseases were investigated under controlled conditions. These experiments showed conclusively that fingerling trout can be subjected to routine preventive treatments at weekly intervals without incurring any increase in mortality.

In two series of experimental infections the common protozoan parasite Cyclochaeta was allowed to increase to epidemic proportions and various treatments in common use were then administered to determine their relative value. In most cases the treatments failed to produce the beneficial effects commonly ascribed to them. Common salt and the use of a malachite green solution at a concentration of 1,400,000 for 1 hour were more efficacious than other methods tried but even these were not effective in checking the disease. Unfortunately, all experiments had to be terminated early in October owing to the annual egg-taking activities at the station.

Considerable attention has been devoted to a myxosporidian parasite *Henneguya salminicola* Ward, which infests the pink and silver salmon of the Pacific coast. This parasite forms white cysts in the body muscles which, when abundant, give rise to the condition known locally as "tapioca." In some sections of Alaska a considerable percentage of the pink salmon may be infected with this parasite.

A disease caused by a myxosporidian parasite of the genus Myxobolus was found among bass fingerlings and brood fish at the Bureau's station at Miles City, Mont. It is claimed that the infection has been gradually increasing, its occurrence being estimated at 20 percent this year. The lesions appear as conspicuous lumps on the back and tail of infected fish. Since Myxosporidia require no intermediate host for completion of the life cycle it is feared the distribution of bass fingerlings from the Miles City station will result in widespread dissemination of the parasite. Studies on the parasite are being continued in the hope of developing some practical method of control.

The Disease Service maintained for assisting State, Federal, and private fish culturists in the solution of their disease problems has increased in popularity. Over 200 shipments of preserved specimens were sent to the Seattle laboratory for diagnosis and a large number of shipments were also received at the Washington laboratory.

# INVESTIGATIONS IN INTERIOR WATERS

DR. M. M. Ellis, in charge

#### POLLUTION STUDIES

Over 150 new localities have been investigated in the course of the stream pollution studies made by the staff of the Columbia, Mo., unit during the past year, and observations have been continued at some 70 old stations. The routine analyses and bioassays required to test and standardize the effluents and samples collected have occupied the time of five laboratory workers under the direction of an aquatic physiologist throughout the year. The combined data from these field and laboratory studies of pollution and polluting substances have been applied to fisheries problems in three ways. Using these data as a scientific background 43 major cases of stream pollution in North Carolina, South Carolina, Delaware, Virginia, Mississippi, Alabama, Louisiana, Texas, California, Oregon, Washington, Idaho, Montana, South Dakota, and New York, have been investigated this year by field parties from the Columbia, Mo., unit and reports have been prepared, or are in the process of preparation, for the guidance of officials and industries involved; over 200 answers to queries from State officials, manufacturers and others interested in particular pollution problems have been sent out; and understanding of the actions of industrial pollutants, particularly of dye wastes, pulp and rayon effluents, petroleum waters and mine waste has been materially advanced. The voluntary cooperation of many manufacturers in the practical application of these findings to definite pollution problems and in the following of recommendations for the elimination of pollution nuisances has been most gratifying.

This year's work has carried the pollution survey into several new States so that every State in the Union and all of the important river systems have now been included in the investigations. The field and laboratory work has been completed for the second part of the pol-

lution bulletin.

The basic physiological studies of salmonids, bass, and catfish on which the applications of the pollution analyses and assays are made have been continued and extended to include the physiological reactions of fishes of these three groups to the minute quantities of the less abundant substances present in stream, lake, and impounded waters. Extensive experimental tests utilizing special apparatus developed for these physiological studies have been carried on throughout the year and are still in progress at the Columbia laboratories, and as a part of this work large series of catfish are being maintained under experimental conditions at Ft. Worth, Tex., by two members of the staff of this unit.

These physiological experiments have directed attention to the cumulative effects of prolonged exposures to very small quantities of substances which are apparently without immediate action on the fish. The tests with fluorides, for example, which are found in small quantities in many waters in the southwest, have shown that continuous exposure to even small quantities of these salts as found in some of the southwestern streams produces definite detrimental changes in the reproductive system and in the musculature of the fish, thereby impairing both the fertility of the fish and the quality of its flesh. Technical

publications on these salts and several others will appear soon.

The field work correlated with these physiological studies of individual fish has involved the investigation of bog-fed streams, streams of glacial origin, mountain streams, and western impounded waters. Detailed surveys of the waters of Elephant Butte Reservoir, Lake Mead, and several of the smaller western impoundments were made during the summer in cooperation with a committee of the National Research Council and definite investigational programs were initiated at Elephant Butte and Lake Mead. This work was then continued in several western streams, including the Colorado, Columbia, and upper Missouri systems. Although not yet completed, practical applications of these studies have already appeared in connection with the stocking programs of various western streams on which impoundments are being built or are contemplated, and explanations have been obtained concerning the unproductiveness of certain reservoirs and streams in these regions. Twenty-five sets of analyses and assays have been made already for Federal and State officials to determine the suitability of waters from various springs, wells, and impoundments for fish or for fish hatchery purposes, in view of the physiological findings now available. Special equipment, not available heretofore, has been devised for the mobile field laboratories, and some of the physiological studies of the fish can now be made in the field.

#### MUSSEL PROPAGATION

The previous plantings of fresh-water mussels reported last year have been followed and extended. The observations to date show much better survival of the yellow sand shells than of the muckets. This may be due in part to the fact that the yellow sand shells grow much faster than the muckets and were more readily found. Even local mussel diggers who had not been apprised of the plants remarked on the increase in young yellow sand shells in the localities where plants had been made.

The program of plantings as previously outlined will be continued during the next 3 years, i. e., until a 5-year planting has been completed. At that time complete returns concerning the success of the restocking program will be available. Because an objection was raised by some of the manufacturers to the planting of yellow sand shells, fewer of that species were planted last year, but in view of the greater survival of yellow sand shells as noted above equal numbers of sand

shells and muckets will be planted during the 1938 restocking.

#### ICHTHYOLOGICAL INVESTIGATIONS

Fishes of the Canal Zone and Panama.—Investigations on the Canal Zone and in Panama, begun in 1935, were continued in 1937 in cooperation with the Gorgas Memorial Laboratory and the Panama Canal by Dr. Samuel F. Hildebrand. A period of 3 months was spent in the field. During this time the locks at the Pacific end of the Canal were unwatered, and collections of fish were made (as in the locks at the Atlantic end in 1935). A study of the specimens and data is under way to determine to what extent the Panama Canal and the locks are used as passageways for fishes. Marine fishes have invaded the fresh water of the Canal to a surprising degree, and at least one species has crossed from the Atlantic to the Pacific.

A study of the feasibility of attempting further introductions of American food and game fishes in Gatun Lake (earlier attempts having failed) was made upon the request of the Panama Canal Government. It was decided that previous attempts to introduce fry had failed because of the great abundance of small native predatory fishes. It was therefore recommended that in the future the fish be reared to a length of six inches or more before liberation. Extreme caution must be exercised in the choice of species, because it is highly necessary to conserve the native mosquito-eating top minnows, important in the

control of malaria.

General collections of fishes were made in various sections of Panama, both in fresh and salt water. The study of the fresh water material, which is nearly complete, has resulted in the discovery of several new species and has demonstrated that the fresh water fishes of the Atlantic and Pacific slopes have intermingled in the Canal to some extent and that limited hybridizing of very closely related species has taken place.

American Anchovies.—The study of the American anchovies undertaken by Dr. Hildebrand more than a year ago was continued as other duties permitted. Observations on Atlantic coast species of both North and South America are nearing completion. A few Pacific coast species, closely related to Atlantic species, also were studied.

The study has resulted in the discovery of several new species, in a better understanding of the relationships existing between the various

species, and in a more logical division of genera.

Fishes of Tortugas, Fla.—Because of a desire expressed by the late Dr. William H. Longley shortly before his death, Dr. Hildebrand was requested by the President of the Carnegie Institution to complete a monograph on the fishes of Tortugas. Dr. Longley's studies had extended over many years, but his manuscript was unfinished at the time of his death.

General Systematic Studies.—Revisional studies of the genera of American fishes have been continued by Isaac Ginsburg. With the completion of a paper dealing with certain genera of the difficult family Gobiidae, the majority of the species of this family in American waters have been worked up on a sound scientific basis. In connection with his revisional studies Mr. Ginsburg gave his attention to the species problem, and published a preliminary paper on this question which is of general biological significance.

# INDEPENDENT ACTIVITIES OF THE FISHERIES BIOLOGICAL LABORATORIES

#### WOODS HOLE, MASS.

Although the laboratory of the U. S. Fisheries station at Woods Hole was not open during the summer, a small number of outside investigators were accommodated for limited periods. As usual, the facilities were utilized in connection with the ovster investigations reported upon elsewhere. In addition, the following persons occupied and worked in the laboratory rooms: Dr. Hugh M. Smith, associate curator in zoology, U. S. National Museum, working on completion of report on fresh water fishes of Siam; Dr. Edwin Linton, University of Pennsylvania, helminth parasites of fishes; E. H. Barnes, biologist, Division of Fish and Game, Massachusetts State Department of Conservation, perfecting the methods of hatching and rearing lobsters; Dr. F. G. Hall, professor of zoology, Duke University, assisted by Dr. F. H. McCutchson, State College, Raleigh, N. C., and Dr. J. W. Wilson, Duke University, respiratory function of the blood of marine fishes. Lack of sufficient funds made it impossible to operate the laboratory on the same basis as in the years prior to 1932.

#### BEAUFORT, N. C.

Research.—Facilities for the study of marine fishery problems in the South Atlantic region were provided throughout the year by the Beaufort laboratory. The chief investigations conducted here by the Bureau's staff under the direction of Dr. H. F. Prytherch consisted of experiments and studies with reference to (1) the life history and control of a sporozoan parasite of the oyster, (2) the propagation of diamond-back terrapin, and (3) the utilization of marsh areas for mullet and oyster propagation.

Assistance was given to the following agencies, as indicated, on matters of importance to the fishery industries of the South Atlantic region: U. S. Engineer Department, advisability of deepening and maintaining Drum Inlet and Cape Lookout Inlet as an aid to the fishing industry in Core Sound, N. C.; U. S. Post Office Department.

presentation of evidence pertaining to investigation of operations and claims of Florida oyster promoting concerns; Virginia Commissioner of Fisheries, studies of the reproductive condition of winter dredged crabs from Chesapeake Bay; North Carolina Department of Conservation and Development, practical procedure for continuation of oyster rehabilitation program; Duke University, construction of biological laboratory at Beaufort, N. C., for studies of marine life of this region; Union Carbide and Carbon Corporation, corrosion

tests with stainless steel cable under marine conditions.

Laboratory facilities for marine research have been provided for 11 independent investigators from other institutions who were engaged in the following studies: Dr. H. V. Wilson, professor in the University of North Carolina, behavior of embryonic cells under controlled conditions; Dr. A. S. Pearse, Duke University, crustacean parasites and marine ecology; Dr. W. C. George, University of North Carolina, blood of Echinoderms and Annelids; Dr. Henry Vander Schalie, University of Michigan, the mollusca of the Beaufort area; Dr. H. H. Harkins, Fordham University, attachment of Cirripedia to submerged surfaces; Fred F. Ferguson, University of Virginia, morphology of marine Rhabdocoeles; W. Henry Leigh, University of Illinois, the parasites of marine fishes; Gordon H. Tucker, University of North Carolina, regeneration in certain of the lower invertebrates; J. Albert Fincher, University of North Carolina, cell behavior and embryology of sponges; John C. Ayers, Duke University, respiration of crustacea; George W. Wharton, Jr., Duke University, gregarine development in mud crabs.

Terrapin culture. The terrapin farm or hatchery operated at the U. S. Fisheries biological station at Beaufort is the largest in the world. It has produced more than 116,000 diamond-back terrapin since the artificial propagation of this species was undertaken in 1909. During the summer of 1937, 11,783 baby diamond-backs were hatched in the five concrete breeding pounds surrounding the station. This brood after being cared for under protected conditions for a period of approximately 9 months will be distributed throughout the South Atlantic region in cooperation with the various State conservation departments. Just prior to 1931 the brood stock was increased to 1,775 females and 440 males and since then the hatch of young terrapin has ranged from 10,060 per year to a record production of 13,245 in 1935. Capt. Charles Hatsel has been in immediate charge

of this work since its inauguration.

Though breeding of diamond-back terrapin under seminatural conditions has been very successful, the general results indicate that each adult female has produced an average of only 6.5 young per year whereas twice this number should be expected according to previous experiments with small lots of animals. During the summer of 1937, experiments were conducted under the direction of Dr. Prytherch in which the brood stock was distributed in the breeding pounds in different concentrations and in varying percentages of each sex. It was found that the ratio of males to females, though varying from 1 to 2 to over 1 to 6, had no noticeable effect on egg production in the different pounds. The principal factor appears to be the degree of crowding of the brood stock as shown by the results from 3 similar pounds in which the hatch per female was 3.0, 6.2, and 9.3

with concentrations of 521, 482, and 310 adults per pound, respec-

tively.

The best results were obtained when 310 adult terrapins were confined in a pen 60 feet square, at a ratio of 1 male to 6 females. This lot produced a total of 2,511 young. Two recent collections of wild stock, aggregating 342 invididuals, show that when the terrapin congregate at the natural breeding areas there is a sex ratio of approximately 1 to 6. Of further interest in this connection is the fact that terrapin previously reared from the egg to sexual maturity at the Beaufort station show a ratio of 1 male to 6.4 females.

Studies were also made in the early summer to determine whether a portion of the brood stock, consisting of rather old females, were "boarders" and incapable of egg production. Examination of several marked specimens from the original brood stock which has been in captivity since 1909, showed that each contained from 7 to 9 completely formed eggs and approximately 3 times this number of developing ova of various sizes. The mature eggs taken from these animals were placed in the sand beds used for incubation and showed a hatch of over 85 percent. These observations indicate that diamond-back terrapins are capable of producing a good supply of eggs and young until they are at least 40 years of age.

Utilization of marsh areas for oyster and mullet propagation.—In many parts of the world improved marsh areas and tidal flats are successfully used for fish and shellfish propagation. In cooperation with the Works Progress Administration a project was undertaken to construct a series of marsh ponds in the vicinity of the Beaufort laboratory to determine the value of such structures for increasing the production of oysters, mullet, and possibly other marine animals

in the South Atlantic and Gulf region.

The construction of one large tidal pond, 21/2 acres in extent, and several smaller ponds, 20 by 40 feet, is virtually completed and will be ready for experiments in 1938. A substantial dike 800 feet long separates the large pond from adjacent waters but permits a regular exchange of sea water by means of two tide gates. Each gate is supplied with 9 wire screens of 3 different mesh sizes to retain the young mullet that are to be placed in the pond in the early summer. The general plan is to rear the mullet to marketable size in this experimental pond from which they may be harvested at any time of the year, and to determine from its operation the most satisfactory and practical procedure for producing these fish in commercial quantities in larger ponds or controlled tidal bays. A considerable area of hard bottom, created in the pond by deepening and leveling operations, is suitable for growing oysters and clams and will be stocked with these shellfish. The shells of the oysters generally support a good growth of plant life which serves as a natural food supply for the mullet.

The series of smaller ponds which will be used primarily for oyster culture experiments have been excavated in a representative salt marsh area with adjustable gates for controlling the depth and flow of water. Ordinarily if seed oysters were planted at pond level so as to be exposed to air at times of low water they would produce inferior market stock because of attachment and crowding of subsequent generations. However, by maintaining a minimum depth of

1 foot or more of water in the ponds at all times this trouble can be eliminated as it is under similar natural conditions. In thus controlling the setting of oysters pond areas of protected bottom that are particularly suitable for growing and maturing these shell-fish are created in the marsh. Such areas are greatly needed for the development of oyster culture in the South Atlantic region. Another advantage of this type of pond is the fact that it can be automatically drained at proper intervals for cleaning or harvesting purposes, and particularly for killing, by exposure to air, the boring sponge which is so destructive to oysters on submerged beds in this region. In operation of the ponds, a series of experiments and studies will be made as to the growth rate of oysters and their increase in volume in relation to density of planting, minimum depth of water maintained and the quantity of water supplied by tidal action.

#### APPROPRIATIONS

The biological investigations of the Division of Scientific Inquiry during the calendar year 1937 were conducted with funds provided by the annual appropriation, Inquiry Respecting Food Fishes, and with the aid of small balances, remaining in special funds made available for the fiscal year 1937. The appropriation for 1938 was \$262,000 but required administrative savings of \$30,000 reducing the actual working funds to \$232,000. Travel funds appropriated separately for 1938 amounted to \$27,000. Approximately one-half of each year's appropriation was spent in the calendar year.

The 1937 appropriation was about  $4\frac{1}{2}$  percent greater than for 1936 and the 1938 appropriation provided a further increase (of roughly 50 percent) in available funds. This increase served to offset the nonavailability of emergency and special funds which in 1937 amounted to \$42,456 and to expand existing projects. A statement of

funds for biological investigations is given below:

Project	1937	1938
Regular appropriations:  Commercial fishery investigations Oyster cultural investigations Aquicultural investigations Conserving fish by screens and ladders Washington laboratory and administration Traveling expenses	\$113, 530 19, 200 33, 845 1, 550 3, 875	\$133, 181 50, 579 42, 500 1, 500 4, 240 27, 000
Total	172, 000	259, 000
Allotment for maintenance and operation of vessels_Special funds: York River oyster pollution investigations Shellfish pest control studies Marine fouling studies	26, 300 17, 456 25, 000	29, 000

APPENDIX II TO REPORT OF COMMISSIONER OF FISHERIES FOR THE FISCAL YEAR 1938

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1938

#### ADMINISTRATIVE REPORT SERIES

Since the beginning of the Administrative Report Series, considerable confusion has arisen concerning the system of numbering the separates composing it. much as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No. —." Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 24 were, they are numbered for filing purposes as follows:

- No. 1. Report, Commissioner of Fisheries, 1931.
- No. 2. Alaska Fishery and Fur-Seal Industries, 1930.
- No. 3. Fishery Industries of the United States, 1930. No. 4. Progress in Biological Inquiries, 1930.
- No. 5. Propagation and Distribution of Food Fishes, 1931.
- No. 6. Report, Commissioner of Fisheries, 1932. No. 7. Alaska Fishery and Fur-Seal Industries, 1931. No. 8. Fishery Industries of the United States, 1931.
- No. 9. Progress in Biological Inquiries, 1931.
- No. 10. Propagation and Distribution of Food Fishes, 1932.
- No. 11. Alaska Fishery and Fur-Seal Industries, 1932.
- No. 12. Progress in Biological Inquiries, 1932.
- No. 13. Fishery Industries of the United States, 1932.
- No. 14. Propagation and Distribution of Food Fishes, 1933.
- No. 15. Fishery Industries of the United States, 1933.
- No. 16. Alaska Fishery and Fur-Seal Industries, 1933.
- No. 17. Progress in Biological Inquiries, 1933.
- No. 18. Propagation and Distribution of Food Fishes, 1934.
  - No. 19. Alaska Fishery and Fur-Seal Industries, 1934.
- No. 20. Fishery Industries of the United States, 1934.
- No. 21. Progress in Biological Inquiries, 1934.
  No. 22. Propagation and Distribution of Food Fishes, 1935.
  No. 23. Alaska Fishery and Fur-Seal Industries, 1935.
  No. 24. Fishery Industries of the United States, 1935.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the Report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

<sup>&</sup>lt;sup>1</sup> Appendix II to the Report of the U. S. Commissioner of Fisheries for 1938. Approved for publication June 23, 1938.

# INTRODUCTION

The two main functions of the Bureau in Alaska are the conservation of the fisheries and the protection and management of the furseal herd that has its breeding grounds on the Pribilof Islands. Deputy Commissioner Charles E. Jackson and other officials spent several weeks in Alaska during the 1937 season, observing both fishery and fur-seal activities.

Regulations for the control of commercial fishing to assure an escapement essential for propagation were modified but slightly during the fishing season, and all changes recommended for the revised regulations to be effective in 1938 were of minor importance. generally satisfactory condition of the fisheries is indicated by the fact that the production in 1937 was the third largest on record, the quantity of canned salmon being noteworthy because for the first time in an odd year it exceeded 6,000,000 cases.

A patrol of the fishing grounds was maintained by the Bureau's fleet of 14 vessels and numerous small boats, supplemented by occasional aerial inspections, chiefly during weekly closed periods. Approximately 165 temporary employees served as stream guards during the fishing season, in addition to the regular personnel of about 60 persons, principally wardens and operators of vessels, engaged in the enforcement of the fishery laws and regulations.

Whenever practicable in connection with their patrol duties, Bureau employees gave attention to the improvement of salmon streams, removing log jams and other barriers that prevented the ascent of

salmon to the spawning grounds.

An important phase of the conservation program is the control of predatory trout, which feed upon salmon eggs and fry. was carried on chiefly in the Bristol Bay and Cook Inlet regions, where a bounty was paid for Dolly Varden trout through funds provided by the Territorial Legislature and by the local salmon packers. Some predatory trout were taken also by Bureau employees in connection with weir operations.

Biological studies of the salmon and herring were continued, and similar investigations in regard to predatory trout were begun in the Kodiak region with a view to obtaining data as a guide to a rational

control program.

Attention was given by the Department of Commerce, in cooperation with the Department of State and other Government agencies, to the problem of averting the threatened encroachment on the Alaska salmon fisheries so as to assure the protection and perpetuation of the

important food resource and industries involved.

There were 55,180 fur-seal skins taken at the Pribilof Islands in 1937, or 2,734 more than in the previous year. The computed number of animals in the herd as of August 10, 1937, was 1,839,119, as compared with 1,689,743 in 1936. Incidental to the fur-seal industry, the feeding and management of blue-fox herds on the Pribilof Islands

was continued. During the 1937-38 season 863 fox pelts were obtained, and a suitable number of animals were reserved for breeding

stock.

The byproducts plant on St. Paul Island was again in operation and yielded 29,830 gallons of fur-seal oil and 165 tons of meal. The oil was sold in Seattle for commercial purposes, and the bulk of the meal was made available for fish food at Federal hatcheries throughout the country.

A few additions and improvements were made to buildings at the Pribilof Islands for use of natives and in the sealing industry. Roads to facilitate the delivery of sealskins from the hauling grounds to the curing stations were extended on both St. Paul and St. George Islands. A substation was established on one of the western Aleutian Islands to provide for the expansion of sea-otter investigations and patrol.

On August 10 the Bureau took over the operation of the radio station on St. Paul Island, which had been maintained previously by the Navy Department and which was transferred to the Department of

Commerce under a revocable permit.

The U. S. S. Sirius transported the annual shipment of supplies to the Pribilof Islands and brought out the season's take of sealskins and a number of passengers. Cooperative service was rendered also by the Coast Guard in maintaining a patrol for the protection of the fur-seal herd, and in performing other important service.

Acknowledgment is made of the assistance by members of the

Bureau's staff in the preparation of this document.

# VISIT OF DEPUTY COMMISSIONER OF FISHERIES, AND OTHER OFFICIALS, TO ALASKA

Deputy Commissioner Charles E. Jackson sailed from Seattle for Alaska on July 1 aboard the *Brant* to inspect the Bureau's fishery and fur-seal activities. The party accompanying him on this trip included Ward T. Bower, Chief of the Division of Alaska Fisheries; Leo D. Sturgeon, of the Department of State; and Jack McFall, Assistant Clerk of the House Appropriations Committee. W. C. Arnold, representing the salmon-canning industry, joined the party at Ketchikan, whence the journey was continued westward to Unalaska, via Sitka, Kodiak, Larsen Bay, Sand Point, False Pass, and Akutan.

At Unalaska, on July 14, Messrs. Sturgeon and Arnold transferred to the Coast Guard patrol boat *Daphne* for a cruise in Bristol Bay, primarily for the purpose of observing operations of Japanese floating canneries. They arrived at Naknek on July 16, and in due time returned to Unalaska, and thence by commercial steamer to south-

eastern Alaska and Seattle.

Deputy Commissioner Jackson and others of the party boarded the *Penguin* at Unalaska on the evening of July 14, and on the following day proceeded to the Pribilof Islands to inspect the Bureau's sealing activities. On July 18 the *Penguin* transported the party to Naknek. After observing fishery activities in the Bristol Bay district, both by vessel and airplane, Mr. Jackson and his party crossed the portage to Iliamna Bay, on Cook Inlet, where they reembarked on the *Brant*. Stops were made at Anchorage, Seward, College Fiord, Cordova, Yakutat, Juneau, Petersburg, Wrangell, Anan Bay, and Ketchikan, and the vessel arrived at Seattle on August 8. After a visit to Port-

land and an inspection of the Bonneville Dam, Mr. Jackson left for

Washington, D. C., and arrived there on August 14.

Mr. Bower left the Brant at Ketchikan and remained in southeast Alaska for about 2 weeks, visiting various salmon canneries and assisting in an aerial inspection of spawning grounds. Before returning to Washington he spent some time at Seattle and San Francisco conferring with members of the fishing industry in regard to Alaska matters. arrived at Washington, D. C., on September 20.

Senator Ernest Lundeen, of the Committee on Territories and Insular Affairs, made an official tour to southeast Alaska on the Brant, sailing from Seattle on August 31 and returning there on September 21. Among the places visited were Ketchikan, Petersburg, Kake, Washington Bay, Warm Springs Bay, Todd, Sitka, Skagway, Haines, Taku Harbor, Hobart Bay, Port Houghton, and Wrangell.

# PROTECTION OF WALRUSES AND SEA LIONS

A new (eighth) edition of Department of Commerce Circular No. 286 was issued under date of July 1, 1937, containing the laws and regulations for the protection of walruses and sea lions in Alaska. The prohibition on the killing of walruses was extended to cover the period from July 1, 1937, to June 30, 1939, and no change was made in the regulations previously in effect concerning the killing of sea lions. Walruses may be taken only by natives for food or clothing, by miners or explorers when in need of food, or by collectors of specimens for scientific purposes under permits issued by the Secretary of Similar conditions apply in respect to the taking of sea lions, and their killing is permissible also in the necessary protection of property or while the animals are destroying salmon or other food fish.

JAPANESE VESSELS IN BERING SEA

Operations of Japanese floating plants in Bering Sea were begun in 1930 and have been carried on each season since then, primarily

in the taking and canning of spider crabs.

Three such plants were operated in 1937: The Taihoku Maru, with 12 bottom trawlers varying in size from 75 to 150 feet; the Toten Maru, with 8 launches and 1 crab-trap planter; and the Taiyo Maru, with 3 auxiliary vessels. Of these, the Taihoku Maru (about 8,000 tons) engaged in the crab fishery in Bering Sea in 1930 and returned again in 1933 and in each season thereafter, its operations in later years being expanded to include the manufacture of oil and meal from bot-The Toten Maru, originally the Nagato tom fish taken by trawling. Maru (about 3,000 tons), had previously operated in the Bering Sea crab fishery in 1931, 1932, 1934, and 1936. The Taiyo Maru was employed in Bering Sea waters for the first time in 1937, apparently continuing the studies of the routes and availability of salmon in offshore waters which had been begun by the Tenyo Maru in 1936. The Taiyo Maru was observed about 20 miles west of Ugashik Bay, with its three auxiliary vessels each operating gill nets about 2 miles

In addition to the foregoing, the Hakuyo Maru, training ship of the Imperial Fisheries Institute of Tokyo, again cruised in Bering Sea for the purpose of affording practice to a group of students in deep-sea fishing, navigation, and seamanship. This vessel has a comprehensive library and oceanographic equipment for scientific study of marine life in all its branches. There is also a small outfit for experimental canning of salmon and crabs. The captain and a party from the *Hakuyo Maru* visited St. Paul Island on July 8 to

observe fur-seal life on the rookeries.

In view of the Japanese activities with respect to the salmon fishery, widespread alarm was aroused among Bristol Bay packers and others concerned lest the interception of the salmon runs bound for Alaska streams should jeopardize and ultimately destroy the long-established Bristol Bay salmon industry. Strong protests were made against the threatened encroachment on the Alaska salmon fisheries, and bills were introduced in Congress and extensive hearings were held, looking

to the protection of American interests.

This whole problem has been the subject of diplomatic negotiations with the Japanese Government over a long period. As a result of these negotiations the Secretary of State announced in March 1938 that the Japanese Government has given assurances (1) that it will suspend its official survey of salmon fishing in the waters of Bristol Bay and (2) that it will continue to suspend the issuance of licenses for vessels to fish for salmon in these waters; and that if and when conclusive evidence is presented that any Japanese vessels engage in salmon fishing commercially in these waters, the Japanese Government is prepared to take necessary and proper measures to prevent such operations.

The American Government will continue to give constant and practical attention to ways and means to assure the protection and perpetuation of the highly important food resource and industries

involved.

#### FISHERY INDUSTRIES

As in corresponding reports for previous years, the Territory of Alaska is here considered in the three coastal geographic sections generally recognized, as follows: (1) Southeast Alaska—embracing all that narrow strip of mainland and the numerous adjacent islands from Portland Canal northwestward to and including Yakutat Bay; (2) central Alaska—the region on the Pacific from Yakutat Bay westward, including Prince William Sound, Cook Inlet, and the southern coast of Alaska Peninsula, to Unimak Pass; and (3) western Alaska—the north shore of the Alaska Peninsula, including the Aleutian Islands westward from Unimak Pass, Bristol Bay, and the Kuskokwim and Yukon Rivers. These divisions are solely for statistical purposes and do not coincide with areas established in departmental regulations.

Detailed reports and statistical tables dealing with the various fishery industries are presented herewith, and there are also given the important features of certain subjects of special investigation or

inquiry.

# LEGISLATION REGARDING NEW HALIBUT TREATY

An act was approved by the President on June 28, 1937, giving effect to the revised convention between the United States and Canada for the Preservation of the Halibut Fishery of the Northern Pacific Ocean and Bering Sea which was signed at Ottawa on January 29, 1937, and became effective with the exchange of ratifications on July

28, 1937. The new treaty contains only two major changes from the former, namely, that the International Fisheries Commission is empowered (1) to legalize the sale of halibut taken by vessels fishing for other species during closed periods for halibut fishing and (2) to prescribe the final date of departure of a halibut boat from port instead of specifying a closing date for halibut fishing. The latter change would permit a vessel on the banks to remain at sea until a full catch is made.

The enabling act, besides giving effect to the treaty and the regulations adopted thereunder, closes markets of the United States to fish taken by any vessel not of American or Canadian registry engaged in halibut operations, and forbids the outfitting or provisioning of any such vessel by persons within the territory or jurisdiction of the United States. The act further makes it unlawful for any person within the territory or jurisdiction of the United States or any American within convention waters knowingly to possess any halibut taken, transferred, received, or brought in, in violation of provisions of the convention or the act.

# ALASKA FISHERIES LEGISLATION

In August 1937 the President approved two acts further amending the Fisheries Act of June 6, 1924. The first of these, approved on August 2, 1937, authorizes the Secretary of Commerce to lease bottoms in the Territorial waters of Alaska for commercial oyster culture, while the second, approved on August 14, 1937, restricts commercial salmon fishing in Bristol Bay by means of stake or set nets to persons who have resided continuously for 5 years within 30 miles of the place where such fishing is carried on.

Oysters were first introduced into Alaskan waters in 1931, when about 40 bushels from Puget Sound were planted in the vicinity of Ketchikan. Since that time about 2,000,000 seed oysters have been planted in Alaska, and in all instances a healthy growth has been reported. It is expected that the legislation making it possible for oyster growers to gain exclusive fishery rights on oyster bottoms will

give impetus to the new industry.

The new law restricting stake and set net fishing for salmon in Bristol Bay is expected to benefit the bona fide residents of that area, particularly those who are physically unfit to engage in operations with drift nets in offshore waters.

The text of the amendments is as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section 1 of the Act of Congress approved June 6, 1924, entitled "An Act for the protection of the fisheries of Alaska, and for other purposes" (43 Stat. 464), as amended by the Act of Congress approved June 18, 1926 (44 Stat. 752), is further amended by striking the period after the words "Alaskan Territorial waters," where they occur at the end of the second proviso, and inserting a colon in lieu thereof and after the colon the following: "Provided further, That the Secretary of Commerce, in his discretion, and upon such terms and conditions as he may deem fair and reasonable, is hereby authorized to lease bottoms in Alaskan Territorial waters for bona fide oyster cultivation for commercial purposes."

Approved, August 2, 1937.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section 1 of the Act approved June 6, 1924, entitled "An Act for the protection of the fisheries of Alaska, and for other purposes" (43 Stat. 464), as amended, is further amended by inserting in said section

at the end of the first proviso thereof another proviso to read as follows: "Provided further, That in the area embracing Bristol Bay and the arms and tributaries thereof, no person shall at any time fish for or take salmon with a stake net or set net, for commercial purposes, unless such person shall have theretofore continuously resided for the period of at least five years within a radius of thirty miles of the place where such net is staked or set:"

Approved, August 14, 1937.

#### NEW FISHERY REGULATIONS

The regulations for the protection of the fisheries of Alaska, issued February 8, 1937, were amended by the following regulations issued by the Acting Secretary of Commerce under the dates indicated:

[July 13, 1937]

#### PRINCE WILLIAM SOUND AREA

Salmon fishery.—Regulation No. 12 (w) is amended to read as follows: "Hinchinbrook Island: Within one-half statute mile eastward of a point on the south side of Port Etches at 146 degrees 40 minutes west longitude."

[July 30, 1937]

# PRINCE WILLIAM SOUND AREA

Salmon fishery.—Regulation No. 10 is amended to read as follows: "Commercial fishing for salmon is prohibited during the remainder of each calendar year after 6 o'clock antemeridian August 2: Provided, That this prohibition shall not apply (a) to trolling and gill netting through August 22 in the waters along the western coast from the outer point on the north shore of Granite Bay (known as Granite Bay Point) to the light on the south shore of the entrance to Port Nellie Juan, (b) to trolling in the period from 6 o'clock antemeridian August 5 to 6 o'clock postmeridian September 20 in the waters of Prince William Sound east of 147 degrees west longitude, exclusive of all waters of Valdez Arm north of Point Freemantle, and (c) to the operation of set or anchored gill nets in the period from 6 o'clock antemeridian August 5 to 6 o'clock postmeridian September 20 in the waters of Valdez Arm east of 146 degrees 25 minutes west longitude. All trap leads from shore to entrance of hearts must be removed prior to 6 o'clock antemeridian August 6."

[August 23, 1937]

#### SOUTHEASTERN ALASKA AREA

#### CLARENCE STRAIT DISTRICT

Salmon fishery.—1. Regulation No. 6 is amended so as to prohibit commercial fishing for salmon, other than trolling, north of a line extending from Narrow Point to Ernest Point from 6 o'clock postmeridian August 26 to 6 o'clock antemeridian October 1, and for the remainder of the calendar year after 6 o'clock post-

meridian October 15.

2. Regulation No. 7 is amended so as to prohibit commercial fishing for salmon, other than trolling, between a line extending from Narrow Point to Ernest Point and a line extending from Approach Point to Caamano Point from 6 o'clock postmeridian August 24 to 6 o'clock antemeridian October 1, and for the remainder of

the calendar year after 6 o'clock postmeridian October 15.

[August 26, 1937]

#### SOUTHEASTERN ALASKA AREA

#### SOUTH PRINCE OF WALES ISLAND DISTRICT

Salmon fishery.—Regulation No. 6 is amended so as to prohibit commercial fishing for salmon, other than trolling, from 6 o'clock postmeridian August 27 to 6 o'clock antemeridian October 1, and for the remainder of the calendar year after 6 o'clock postmeridian October 15.

Revised regulations effective in 1938 for the protection of the fisheries of Alaska were issued by the Secretary of Commerce under date of February 15, 1938, copies of which may be obtained, without cost, on application to the Bureau of Fisheries, Washington, D. C.

# ANNETTE ISLAND FISHERY RESERVE

The Annette Island Canning Co. again operated the salmon cannery at Metlakatla, under its lease from the Department of the Interior.

Eight salmon traps were operated by the company, the total catch of which numbered 1,561,077 salmon, and 71,414 salmon taken by seines and gill nets in the waters of the reservation were purchased from natives. In addition, 1,100,965 salmon were purchased from independent operators of seines and traps outside the reserve. Of the total number of fish obtained, 142,379 were sold to other canneries, and the remainder were packed at the company's plant. In the operation of the cannery and fish traps, employment was given to 89 whites and 333 natives.

Profits to the Metlakatlan Indians of the reserve on the cannery operations for 1936, under the provisions of the lease, amounted to \$73,551.83. Preliminary estimates for the year 1937 place the figure

at about \$111,700.

# STREAM IMPROVEMENT

No special project of improving salmon streams was undertaken in southeast Alaska in 1937, but stream watchmen, in connection with their regular patrol duties, continued to clear out log jams and windfalls that impeded the ascent of salmon to the spawning beds. They also cut trails along the banks of the streams to facilitate inspection

of the spawning grounds at the close of the season.

Elsewhere in Alaska, also, stream-improvement work was limited, for the most part being incidental to the patrol of the fishing grounds. In the Cook Inlet district, however, considerable work was accomplished at Cottonwood Creek and Fish Creek, together with their numerous tributary streams and lakes, through funds provided jointly by the Territory and the salmon packers of the district. These creek systems provide extensive spawning grounds for red and coho salmon, but within the last 3 years they have become infested with beaver dams, which in most cases constitute barriers to salmon migrating to the spawning grounds, if not kept open during the runs. Mr. George S. Mosier, a resident of Matanuska Valley for many years, was employed from June 21 to August 15 to keep open the various small streams connecting the lakes so that all spawning grounds would be available for seeding.

# CONTROL OF PREDATORY TROUT

The destruction of trout that feed upon salmon eggs and fry was carried on, as heretofore, with funds allotted from appropriations by the Territorial Legislature and matching contributions by salmon packers of certain districts. The Territorial appropriation in 1937 for clearing streams and the destruction of predatory enemies of salmon during the biennium ending March 31, 1939, was \$25,000. Most of this amount was allotted for control of predatory trout in the Bristol Bay region, where the work has been conducted for a long

period and is considered responsible for a part of the gains in the red-

salmon runs in recent years.

During the year 1937 approximately \$20,000 was expended in the Bristol Bay region for bounty on Dolly Varden trout at the rate of 2½ cents per fish. The Bureau maintains a staff of five representatives in this district, one in each watershed, to receive, count, and destroy the trout tails presented and to issue the vouchers upon which payments are made by the Territorial Treasurer. Only bona fide residents of the district are engaged in the taking of trout, and the bounties provide an important means of livelihood during the winter.

A bounty of 2½ cents each was paid, also, for Dolly Varden trout taken in the Kasilof River, English Bay stream, and the red salmon streams on the east coast of Kalgin Island, in the Cook Inlet area. It was deemed advisable to confine efforts in this district to a few streams in order to determine what the possibilities may be. The total number of trout tails from these streams for which vouchers had been made to August 27, 1937, was 8,888. It is anticipated that a much greater interest in the work will be taken by the local residents during the 1938 season.

The destruction of Dolly Varden trout was carried on in the Kodiak area in streams in which weirs were operated. Traps built of fine mesh wire were installed in connection with the weirs and were very effective in catching the trout. During the year 81,539 trout were caught and destroyed at Karluk, 95,795 at Red River, and 40,803 in

Olga Bay streams.

In the Kodiak area studies were undertaken to develop further information in regard to the migratory habits of Dolly Varden trout. At the Karluk weir site, during the seaward migration, 4,709 trout were tagged by inserting a numbered metal tag in the body cavity, and 427 trout were marked by removing the adipose and right ventral Traps for the capture of upstream Dolly Varden migrants were maintained from July 16 to September 9; the catch was examined for the presence of marked and tagged fish, and 626 specimens were preserved for future study. Of the upstream migrants, 966 were tagged and released. At the Red River weir 1,862 Dolly Varden trout were marked and released during the seaward migration, and later in the season 330 marked specimens were taken from the upstream migration and preserved for future study. Of the upstream migrants at Red River, 1,600 were marked and released. These tagging experiments and studies will be continued in the following season, with a view to determining the effect of predatory control work in one stream on the trout populations of adjacent streams, in order to provide a guide for a rational control program.

#### STREAM MARKING

Before the opening of the commercial salmon-fishing season, and during the course of the regular patrol, markers showing closed areas and the closed waters off the mouths of salmon streams were inspected in all districts. Repairs and replacements were made whenever necessary, and positions were altered or new markers erected to conform with changes in the regulations.

The warden on the west coast of Prince of Wales Island reported that as a result of having placed new markers at least 12 feet from the ground in 1936 and having removed the lower branches of the trees on which such markers were nailed, the number of defaced and missing markers that had to be replaced in 1937 was greatly reduced.

In the Kodiak area the anchoring of two buoy kegs 100 yards off the mouth of Karluk River to designate the boundary of the closed waters proved very helpful in preventing fishing in the restricted area. Similar buoys anchored off the mouth of Red River likewise were effective in preventing illegal fishing. The fishermen know that if they are found operating inside the buoy markers they cannot claim it was without their knowledge and intent because of inability to judge their distance by the markers on shore.

# STREAM GUARDS

The Bureau employed 165 men in 1937 as stream guards, weir operators, and special workmen in connection with law-enforcement duties. Of these, 84 were stationed in southeast Alaska, 53 in central, and 34 in western Alaska. Some of the workers were engaged for only a few days, but the average period of employment ranged from 2 to 5 months.

In southeast Alaska 34 stream watchmen furnished their own launches and were assigned to patrol larger bodies of water or in the

vicinity of several streams.

In central Alaska 10 guards were stationed in the Seward-Katalla district, 9 on Cook Inlet, 23 in the Kodiak-Afognak district, 4 at Chignik, and 7 in the Ikatan-Shumagin district. Nine of these guards, most of whom were in the Seward-Katalla district, furnished their own launches.

In western Alaska 33 were on Bristol Bay and 1 in the Yukon-

Kuskokwim district.

There were also 8 special employees engaged in scientific work—2 on herring and 6 on salmon investigations, this work being carried on in southeastern and central Alaska.

In addition, there were 12 statutory employees, 49 men on the

Bureau's vessels, and 2 on the chartered boat.

The foregoing makes a grand total of 236 persons identified with fishery protective work in Alaska in 1937, as compared with 249 in 1936.

#### VESSEL PATROL

Fourteen vessels of the Bureau were engaged in the Alaska fisheries patrol in 1937. Of these, the Auklet, Kittiwake, Merganser, Murre, and Widgeon were used in southeast Alaska; the Eider was in the Kodiak area; the Ibis at Chignik; the Red Wing in the Alaska Peninsula area:

and the Coot on the Yukon River.

The Blue Wing assisted in replacing stream markers in the Ketchikan district, southeast Alaska, for a short time in the spring, and during the remainder of the season patrolled Prince William Sound. After being used in herring-tagging operations in southeast Alaska in the spring, the Teal carried on the patrol in Cook Inlet from May to August, inclusive, and participated in the patrol on Prince William Sound during most of the month of September. At the beginning of the year the Crane was in the service of the Post Office Department until February 4, transporting mail between Seattle and Juneau during the maritime strike. The Crane carried Bureau employees and

supplies to Bristol Bay in May, and then patrolled the Alaska Peninsula area until the 1st of August, when it returned the Bristol Bay

crew to Seattle.

The Scoter patrolled the Bristol Bay area during June and July. On August 5 it relieved the Crane in the Alaska Peninsula area, and after the close of the fishing season there it was used in the Kodiak area from about the middle of August to September 17. En route south the Scoter assisted with the stream inspection on the west coast of Prince of Wales Island before returning to Seattle. The Scoter engaged in the fur-seal patrol off Cape Flattery, Wash., for about 2 weeks in the latter part of March and the first of April, during the northward migration of the Alaska fur-seal herd.

The *Brant* was used for the most part in general supervisory work, making five round trips between Seattle and Alaska during the year. Except for the cruise to the westward as far as Dutch Harbor in July, with the Deputy Commissioner's party, the *Brant's* work in Alaska was confined to the southeastern district. The vessel participated in the patrol and survey of spawning streams during the fall

season.

As in the previous year, four speed boats were in operation, one each on Bristol Bay, in Prince William Sound, in the Wrangell district, and in the vicinity of Juneau. Nine other small power boats also were in use, including a number of skiffs equipped with outboard motors. Of these, four were used on Bristol Bay, two at Kodiak, one on Cook Inlet, one in the Seward-Katalla district, and one on the

west coast of Prince of Wales Island.

In addition to the foregoing, the Wingham was again chartered for patrolling the Copper River flats and, at the close of activities there, for use in the general patrol and examination of salmon streams in Prince William Sound. A gas boat was chartered to patrol Uyak Bay, in the Kodiak area, during the pink-salmon run. In the Alaska Peninsula area the Alasco II was lent to the Bureau for several days patrol of the region from Orzenoi to Pavlof Bay. A small power boat was hired to patrol the Egegik district of Bristol Bay, the boat previously used there having been condemned and sold.

#### AERIAL PATROL

The Bureau's use of airplanes, chartered from commercial companies for patrolling the fishing grounds, was somewhat less extensive in 1937 than in the previous year, but a number of violations of the fishery laws and regulations were detected by this means. Aside from the speed in making observations over large areas, perhaps the chief value of aircraft as an auxiliary to the vessel patrol is that it acts as a deterrent to illegal operations, both because the fishermen do not know which plane may be engaged in the air patrol and because they have insufficient time to adjust their apparatus at the approach of an investigator.

The aerial patrol in 1937 was carried on in Bristol Bay, in Prince William Sound, and in the Juneau and Ketchikan districts of southeast Alaska, chiefly during closed periods. Airplanes were used at times, also, for the inspection of the spawning grounds and for transporting Bureau officials to isolated districts. During the 1937 season 9,335 nautical miles were traveled in these activities, on 31

days, the total flying time amounting to 91 hours. In addition, transportation was provided during regular passenger flights comprising approximately 10 hours of flying time.

# COMPLAINTS AND PROSECUTIONS

A floating trap of Libby, McNeill & Libby on the west coast of Prince of Wales Island in San Christoval Channel was found fishing during a weekly closed period. The watchman stated that he had opened it at 6 p. m. on Sunday, thinking that the weekly closed period was the same for salmon as for herring fishing. Upon trial in the local Commissioner's court the company's superintendent pleaded guilty to illegal fishing and a fine of \$1,000 was imposed.

Operators of six trolling boats were tried in Commissioner's court and convicted of fishing during a weekly closed period off Granite Point, Baker Island. In the case of the Voyager, the two fishermen were fined \$25 each, and fish aboard the boat were seized and sold for \$120. Similar fines were imposed on two fishermen on the Leda, and sales of seized fish from that boat also brought \$120 for the account of the Government. Fines were placed at \$50 each in the case of the trolling boats Traveler II and Helen A, and \$125 in the case of the Valid. The operator of the last-named boat did not proceed to Craig when ordered, but resumed fishing on the following day, although fully aware that he had violated the regulations. Two fishermen on the Gravina were assessed \$150 each, a higher fine being imposed because they disregarded instructions and proceeded to Wrangell to sell their catch before appearing in the Commissioner's court at Craig to answer charges of illegal fishing.

Fourteen seine boats in southeast Alaska were apprehended for illegal fishing, and the operators were tried in Commissioner's court. Of these, six men on the St. Joseph were fined \$100 each for fishing after the close of the season within 500 yards of a salmon stream in Mink Bay, and five men on the Tennessee were fined \$40 each on

similar charges, this being their first offense.

The Souvenir and Rikka R were found fishing in closed waters within 500 yards of the mouth of a salmon stream—the former in Port St. Nicholas and the latter in Keete Inlet, and the 31A125 was using a short seine in Klakas Lake stream. Live fish in the seines were returned to the water, and no salmon were confiscated. Each of these three boats had a crew of four, and fines totaled \$600, or \$50 for each fisherman. A fine of \$50 was assessed in the case of the seine boat Bear for using a seine shorter than the specified minimum length permitted. Five operators on the Peter A were fined \$100, or \$20 per man, for fishing in closed waters inside the markers of Big Salt Lake. A short seine, 35 fathoms, was found in Klakas Lake stream, the owner of which was not apprehended. This and other short seines found in use by fishermen along the west coast of Prince of Wales Island were confiscated and destroyed.

Three fishermen on the *Ramona* were fined \$25 each for fishing in closed waters at the mouth of a salmon stream about 1 mile south of Cape Strait, Frederick Sound, and five men on the *Grace* were fined a total of \$125 and costs of \$40.80 for fishing in Tom Creek, Bradfield Canal. Three purse-seine boats, the *Emerald*, *Howard B*, and *Nebraska*, were seized for fishing in a weekly closed period in

Pleasant Bay, Seymour Canal. The defendants pleaded guilty in Commissioner's court and fines of \$200 for each boat were imposed. The operator of the *Ovin* was fined \$515 for a similar offense and for attempted bribery of the stream guard who made the arrest.

A case against operators of the seine boat New England, charged with fishing commercially in a closed area in Saginaw Bay, was tried in the Commissioner's court at Juneau and dismissed because of

insufficient evidence.

Two gill-net fishermen, operating the boat 31B172 in the Wrangell district, were found guilty on two counts—fishing in a closed area in Kah Sheets Bay and blockading a stream with staked gill nets. Fines of \$100 on each count were assessed against each operator, and costs amounted to \$18.60, making a total of \$418.60 for fines and costs.

Fish aboard the boat were seized and sold for \$71.59.

The halibut boat *Bremerton* was found fishing in closed waters off Noyes Island on Sunday July 25. The case was tried before the United States Commissioner at Craig, and a fine of \$750 was assessed and paid. The halibut boat *Reliance I*, of Ketchikan, was fined \$800 in Commissioner's court at Sitka for violation of the halibut fishing regulations. The vessel had cleared for fishing in Area 3 and was found fishing in Area 2 by the Coast Guard cutter *Haida*.

Charges were brought against the Lindenberger Packing Co. of Craig for canning salmon that had been out of the water more than 48 hours. The case was still pending at the end of the year. Another case still pending is that against Frank Richardson, charged with fishing with a small seine in closed waters in the Wrangell district.

In the Seward-Katalla district 12 gill-net boats were apprehended for illegal fishing; upon trial in the Commissioner's court convictions were obtained in all cases, and fines were assessed and paid. Operators of four of the boats in question (T-385, 31B778, 31C269, and Pioneer Canneries Co. boat No. 42) were found guilty on each of three counts—fishing in a closed period, in closed waters of Bering River or Bering Lake, and with stake nets, a prohibited type of apparatus in the locality; fines of \$75 each were assessed against the fishermen, or a total of \$450. Sales of salmon seized from three of the boats brought \$213.50 for the account of the Government.

Two fishermen on the *Queen* (31A802) also charged with a triple violation were convicted on two counts, fishing in a closed period and and in closed waters of Bering River, about 6 miles above Point Hey, and were fined \$50 each. The catch aboard the boat was seized and sold for \$60.20. One of the fishermen was later arrested and fined \$50 for fishing without a license, in violation of Territorial law.

The operator of the 31C287 was fined \$25 for fishing in a weekly closed period and his catch was seized and sold for \$19.60. Another fisherman, on the 31B547, was fined \$50 for fishing in a closed period and in closed waters in Bering River; his forfeited catch was sold for \$63. Fines of \$35 against the operator of the T3951 and \$25 each against two operators of the 31B869 were imposed for fishing in a weekly closed period off Russian Slough, and fines of \$25 each were assessed against the operators of Pioneer Canneries boat No. 17 and a skiff for fishing within 500 yards of the Grass Banks at Russian Slough. The operator of the 30J56 was fined \$25 for fishing above markers fixing closed waters west of Cottonwood Point.

Three set gill nets, the owners of which were not apprehended, were found fishing inside Walhalla Slough. The nets and fish were configurated and the letter were sold for \$26.25

fiscated, and the latter were sold for \$26.35.

One prosecution was brought for the taking of undersized clams in the Cordova district. The defendant pleaded guilty before the United States Commissioner and paid a fine of \$25. The illegal catch of clams was sold for \$16.50 for the account of the Government.

A charge was brought against the Premier Salmon Co. for having a floating trap located on a site in Port Etches not open to trap fishing. Upon investigation it was found that a mistake had been made in the regulations describing the area in which trap fishing was permissible and in which this company's trap had been operated continuously for a number of years. Regulations were amended to

properly describe this trap site and the charges were dismissed.

Considerable dispute had arisen in the last year or two at the opening of the fishing season regarding gill-net locations in the Red River area, chiefly in the vicinity of Bumble Bay, where certain fishermen have been unwilling to comply with the practice formerly adhered to, that an individual's right to a location he had operated in the previous year would not be usurped if he were on hand at the opening of the season to resume fishing at that place. When the warden found a number of gill nets in Bumble Bay too close together on the day the fishing season opened, the operators were given 1 hour to come to an agreement among themselves as to which should move in order to maintain the required distance interval between the nets, and the proper adjustment was made without court action. Later in the season two gill nets were found fishing in Bumble Bay during a weekly closed period. The owner of one of the nets was arrested and taken before the Commissioner's court at Kodiak, where he pleaded guilty and was fined \$50. The owner of the other net was not found. and the net was turned over to the United States marshal for public sale.

In the Cook Inlet area two native fishermen were arrested for fishing on Salamato Beach with gill nets less that the required 600 feet apart. They were tried before the Commissioner at Kenai and fined \$20 each. A fisherman in outboard power dory 31C530 was found fishing in the vicinity of Kenai River with a drift gill net 139 fathoms long, or 39 fathoms in excess of the maximum length permitted on any one boat in this area. Upon trial in the Commissioner's court the defendant pleaded guilty and was fined \$100. His catch of 67 red and 1 king salmon was seized and sold for Government account. Two cases involving three gill-net operators charged with fishing in a weekly closed period were tried before the United States Commissioner at Anchorage: a joint fine of \$50 was imposed on two partners, and the individual operator likewise was fined \$50.

In the Bristol Bay area two fishermen were apprehended for laying out gill nets from a skiff that was being towed by a power boat near Clarks Slough. They were taken before the Commissioner's court at Snag Point, where they pleaded guilty and were fined \$80 each, or 40 days in jail. The fines were paid, and the boats, nets, and fish

were returned to the operators.

Two fishermen on the Alaska Packers Association's boat No. 44 were arrested on July 17 for using gill nets of illegal sized mesh.

Trial was before the United States Commissioner at Koggiung, who imposed fines of \$150 each, ordered the illegal gear destroyed, and denied the violators the right to fish during the remainder of the

season

Four fishermen on two gill-net boats belonging to the Alaska Packers Association were fined \$50 each for fishing in a weekly closed period. Cases against four others operating two boats of the Red Salmon Canning Co. in a similar offense will be tried in 1938, as the men had left for the States before the United States Commissioner could handle the matter at the close of the 1937 season. Ten gill-net boats of the Nakat Packing Corporation were seized for fishing in closed periods. Upon trial before the United States Commissioner the 20 fishermen involved were found guilty and fined \$35 each, which fines were suspended. Two fishermen operating the Alaska Packers Association's boat No. 43J were arrested for laying out drift nets less than 100 yards from the gear operated by another of the company's boats about one-half mile below Koggiung Channel light. The case was heard before the Commissioner and discharged.

A case against the operators of the Alaska Packers Association's boat No. 35 for fishing with a set net in a closed area on the north side of Kvichak Bay was tried and dismissed by the local Commissioner. Another case of this nature against two fishermen operating boat 63J of the Alaska Packers Association will be tried next season, as the men had left for their homes on Iliamna Lake before the case could be brought before the Commissioner. Two cannery shoresmen, found placing a net in the mouth of Prosper Creek, Kvichak Bay, were charged with fishing without a Territorial license, in a closed period.

Upon trial by the Commissioner the case was dismissed.

#### ROBBERY OF FISH TRAPS

Four Ketchikan men charged with the robbery of salmon from traps of the Pacific American Fisheries, Inc., and the Astoria & Puget Sound Canning Co., in the Icy Strait region during the 1937 season were tried in the Federal District Court at Juneau and found guilty. Two of the men were sentenced to 5 years each, and the others to 3 years each, in the Federal penitentiary.

#### TERRITORIAL FISHERY LEGISLATION

At its biennial session in 1937 the Alaska Legislature amended the act of 1935 concerning the establishment of an Alaska planning council for making investigations in regard to the resources of the Territory and recommendations for the conservation, utilization, and development of such resources. The modified act outlines additional duties of the council members and appropriates the sum of \$15,000 for the work

Another act provides for the establishment of a fisheries experimental laboratory in the Territory to aid in developing the unutilized fisheries resources, and particularly to encourage the processing and marketing of such fisheries during the fall, winter, and spring, thus overcoming the handicap of short seasonal employment now suffered in fishing centers. This act also provides for the establishment of a fisheries experimental commission, consisting of the Governor of Alaska, the Alaska agent of the Bureau of Fisheries, and a third

member to be appointed by the Governor, which commission shall select a supervisor of the laboratory, obtain a suitable site and buildings, acquire necessary scientific instruments and equipment, and hire technical and clerical assistants, the amount to be expended for the site and buildings not to exceed \$8,000 and for the instruments and equipment, \$6,000. The sum of \$20,000 to carry into effect the provisions of the act was appropriated, with the proviso that it be made available when the United States, or some department or agency thereof, shall match or agree to match the amount in cash, equipment, or services.

An act was passed repealing subsection 9 of section 3138 of the Compiled Laws of Alaska for 1933, which provided for a tax on fish

buyers dealing in fresh fish.

Appropriations for the payment of bounty on hair seals, in order to prevent their increase and the consequent danger to the maintenance of valuable fisheries, amounted to \$10,000 to cover a deficiency in the appropriation for the biennium ending March 31, 1937, and \$40,000 for the succeeding biennium. The sum of \$25,000 was appropriated for clearing streams so as to improve conditions for the natural propagation of salmon.

# TERRITORIAL LICENSE TAX

Fisheries license taxes were collected by the Territory under the general revenue law of 1921, as amended in subsequent sessions of the Territorial Legislature. A statement from Oscar G. Olson, Territorial treasurer, under date of May 28, 1938, gives the collections made to that date for the year 1937, representing the taxes on operations of the previous year. It was stated that collections under the several schedules were fairly complete, although a few of the fisheries companies had not yet made full settlement.

Fishery license taxes collected by Territory for fiscal year ended Dec. 31, 1937

#### KUSKOKWIM RIVER

The Bureau had no stream guard stationed on the Kuskokwim River in 1937, and reports of operations there are fragmentary. It is understood that the catch by natives in the district was about normal. Robert Gherkie again engaged in commercial fishing and shipped 7,200 pounds of pickled king salmon to the outside market. Upon the basis of the average for the last 4 preceding years, 329 natives fished

in the river for local food requirements, using 290 gill nets of 4,900 fathoms, 45 wheels, and a number of small boats; their estimated output was 349 tons of dried chums.

## YUKON RIVER

Only two outfits on the Yukon River engaged in salting salmon for the outside market—the Northern Commercial Co. in Acharon Channel and St. Mary's Mission at the head of Sunshine Bay. All fish handled by the former were taken in gill nets outside the mouth of the Yukon by native fishermen. The catch of the mission was by wheels in the river.

Inspector Calvin F. Townsend and Stream Guard Charles Mc-Gonagall patrolled the district aboard the Coot. The vessel was launched from the Government ways at Nenana on May 18, but lay at the dock until May 27 waiting for the Yukon River to clear of ice. When the Coot began the journey downstream, the Tanana River was very high and in many places over its banks, making

navigation extremely difficult.

The ice in the Tanana River at Nenana started to run on May 12 and continued until May 17, with the highest stage of water ever known at a break-up. About 20 miles below Nenana the ice jammed, raising the river until the streets of Nenana were about 2 feet under water. After 5 days the ice broke, but it jammed again at the mouth of the Tanana River and held until May 25, flooding the whole country. Nearly every fish camp along the Tanana and Yukon Rivers for a distance of about 200 miles was either washed away or

broken up by the ice.

The high water, resulting from an unusually heavy fall of snow during the winter, continued through June and July and was one of the main causes of the light catches of salmon at the various fish camps. At three places—Pilot Station, Bishop Mountain, and Ruby—the catches were normal, which is accounted for by the fact that the river is confined to one channel at these points. Elsewhere there are many channels and sand bars, and owing to the high stage of the river the salmon did not follow their usual course but kept in the shallower water on the side of the river opposite from the location of the fish wheels. Many wheels were broken by drift wood. In any case the wheel is practically useless during high water.

As a result of the light catches there will be a shortage of salmon for men and dogs in many places. However, white fish and black fish are available there in quantities. After the river lowered in the fall some natives and whites took fairly good catches of salmon in their fish wheels, but most of the men had gone to the hills to hunt caribou.

The first king salmon were caught at the mouth of the river on June 11. The best catch was on June 19, but the runs were light throughout the season. Chums entered the river at the same time as the kings, but none were taken at the saltery. As all streams tributary to the Yukon were at flood stage during the season, it is thought that many spawning beds will be left dry before the eggs have a chance to hatch. Very few beluga whales were observed this year; generally hundreds of them follow the salmon runs up the river. Although good runs of kings and chums usually enter Kwiguk Slough, almost no salmon were found there this summer. In 1927 the run at that place

was a failure, and after an examination of the channels in the following year the scarcity was attributed to the fact that the mouths had

filled with sand.

Products of the Yukon and Tanana fisheries, including those shipped to the outside market, were as follows: 60 cases of king salmon canned; 126 tierces of mild-cured kings; 1,000 pounds of kings and 2,900 pounds of chums pickled; and 225 tons of chums dried. Apparatus consisted of 210 wheels, 112 gill nets of 1,311 fathoms, 4 motor vessels of 36 tons, 7 gill-net boats, 1 scow, and miscellaneous small boats. There were 10 whites and 323 natives engaged in the fishery.

## WEIRS FOR COUNTING SALMON ESCAPEMENT

As a means of determining the ratio of escape to catch and of providing data for use in connection with life-history studies of the salmon, 12 weirs for counting the escapement of salmon to the spawning grounds were operated in Alaska in 1937. This is one more than the number operated in 1936, the upper station weir at Olga Bay having been installed again after being discontinued for 4 years. In addition, a count was made at Kalgin Island Creek without the use of a rack.

Reports of the weir operations and the counts of salmon in 1937

are as follows:

# ALITAK BAY

The cannery station weir on Olga Bay, tributary to Alitak Bay, was ready for operation on May 1 and the first red salmon were counted through on May 29. Counting was continued through September 5, when the total escapement numbered 252,193 red salmon, 5,788 pinks, and 353 cohos.

The upper station weir was not installed before the run began, and the first count there was made on June 15. When the weir was removed on August 16, the total count consisted of 120,828 red salmon and 700 pinks. It was estimated that 25,000 red salmon had ascended

the upper station stream before the weir was in operation.

Commercial fishing in the Alitak region was stopped for 3 days in the second week of August in order to permit the escapement to equal the catch. The run continued in good numbers after the commercial fishing season ended, which assured an escapement well above 50 percent of the run. During the season 40,803 predatory Dolly Varden trout were taken in traps operated in connection with the weirs.

At the beginning of the season the work was carried on by Henry B. Looff; later, A. Morris Rafn was in charge at the cannery station weir, and Harold Greer at the upper station weir, under the supervision of

Warden J. Steele Culbertson.

# CHIGNIK RIVER

The weir in Chignik River was established about 150 feet below the site used in the previous season, where the river is from 2 to 5½ feet deep and about 455 feet wide. Construction was of the usual tripod type, permitting the use of the old material. The weir contained 48 tripods, to the face of which were nailed 3 rows of 4- by 4-inch stringers, about 30 inches apart. Pickets, 2 by 2 inches, spaced 1½ inches apart, were driven into the river bed and nailed to the stringers.

Four 22-inch counting gates and one 72-inch gate for small boats were provided. A 2- by 12-inch plank walk was built along the top of the weir, and a fence of wire netting of 2- by 4-inch mesh and 72-inches in height was stretched above the pickets to keep the salmon from passing over the weir at high tide. A freshet on June 15 caused the structure to sag a little in two places, but there was no serious damage done, and the salmon could not pass through except at the gates.

The first count was made on June 1, when 15 red salmon passed upstream. Throughout the season the run was light, and when operation of the weir was discontinued at the close of September 3 the total escapement consisted of 597,298 red salmon. In addition, 8,887 cohos and 2.250 kings were counted during the season. The largest count

of red salmon for any one day was 25,063, on June 21.

In order to secure an escapement of 50 percent of the salmon run, it was necessary to restrict commercial fishing in Chignik Lagoon and that part of Chignik Bay west of 158 degrees 26 minutes west longitude at three different intervals during the season. These waters were closed to commercial fishing for salmon from 6 o'clock postmeridian July 9 until 6 o'clock antemeridian July 19, from 6 o'clock antemeridian July 30 to 6 o'clock antemeridian August 2, and from 6 o'clock postmeridian August 6 to 6 o'clock antemeridian August 18. The total commercial catch from the Chignik run in 1937 was 580,990.

Warden Charles Petry was in charge of operations at the Chignik

weir.

#### CHINIK CREEK

The weir at Chinik Creek, in charge of Rudolph H. Koch under the direction of Capt. R. L. Cole, was installed on June 24, and the first salmon passed through on July 8. Counting was discontinued on August 1, when the total escapement numbered 8,256 red salmon.

#### ENGLISH BAY STREAM

Construction of the weir in the stream at the head of English Bay was started on May 23 and completed 4 days later. From May 31 to August 3, inclusive, there were counted 14,857 red salmon and 174 pinks. The peak of the run was on July 10, when 1,298 red salmon passed upstream. The work at this weir was carried on by Percy G. Maltbie, under the supervision of Capt. R. L. Cole.

#### FISH CREEK

A weir was again established in Fish Creek on the west shore of Knik Arm, through which 50,617 red salmon and 489 cohos were counted from July 21 to August 9, inclusive. The peak of the run was reached on July 30, with an escapement of 6,351 red salmon. Under the direction of Capt. R. L. Cole, operations at this weir were carried on by Charles E. Jones at the beginning of the season, and later by William E. Conrad.

#### KALGIN ISLAND CREEK

A count of salmon ascending the creek on the east side of Kalgin Island was again made by the stream watchman stationed there. Such counting, without the use of a weir, is possible because the sal-

mon cannot ascend the stream except in the 2 hours before high water and for 2 hours of ebb. This season, however, the water was unusually high and of a brownish color, which made it difficult to observe the escapement accurately. From June 2 to August 6, inclusive, 20,820 red salmon were counted, and it was estimated that the escapement included also from 7,000 to 8,000 salmon that were not counted. In addition, a considerable number were observed at the mouth of the stream when the watchman was removed on August 7.

#### KARLUK RIVER

When the weir in Karluk River was being installed, from May 11 to May 17, the water was exceptionally low for the time of year. King salmon started to pass upstream on May 24 and red salmon on May 27, but there was no appreciable escapement until June 7, after which the run was very heavy for about 3 weeks, with the result that almost two-thirds of the season's escapement of red salmon occurred in the month of June. The largest escapement for any one day was on June 10, when 115,290 red salmon were tallied. When counting was discontinued on October 6, the total escapement numbered 1,265,003 red salmon, 15,666 cohos, 6,882 kings, and 5,738 pinks. It was estimated that 30,000 salmon were still in the lagoon at the time the weir was removed.

The large escapement at the beginning of the season was accounted for by the fact that storms wrecked apparatus and prevented fishing for a period during a heavy early run. As a result, the catch from the Karluk run never did equal the escapement. The total commercial catch of red salmon from the Karluk run was 1,028,730.

Traps for the capture of predatory Dolly Varden trout were operated as usual in connection with the Karluk weir and caught 81,539

of these fish during the season.

James O'Brien was in charge of the weir, under the direction of Warden J. Steele Culbertson.

## KLAWAK CREEK

The weir in Klawak Creek, erected at the same site as in previous years, was completed on June 2. Counting began on June 4 and was continued through September 29, during which time the escapement tallied was as follows: 33,544 red salmon, 572,271 pinks, 13,625 chums, and 2,578 cohos. It was estimated that half the pink salmon and almost all the chums and cohos died at the foot of the falls above the weir because low water made it impossible for salmon to ascend the falls. Arrangements have been made whereby the Forest Service will undertake to improve these falls, probably before the beginning of the salmon run next season. L. M. Johnson was weir foreman at the Klawak weir, under the supervision of Warden Donald S. Haley.

# LITTLE PORT WALTER

A weir was again operated at Little Port Walter, primarily in connection with the study of the pink-salmon runs in southeast Alaska. From August 16 to September 9 there were counted 7,085 pink salmon, 53 chums, 8 cohos, and 3 reds. On September 10 no count was made

because of high water, and the weir structure was washed out that night. It was estimated that about 2,000 salmon were in the river below the weir at that time.

#### ORZENOI RIVER

Construction of the weir in Orzenoi River was begun on June 2 and completed on June 8. A flood took out part of the structure on June 11, and it was not until June 17 that the work of replacing pickets and building an extra flood gate was completed. From June 19 to August 6, inclusive, there were counted through the weir 16,343 red salmon, 6,358 pinks, 1,316 chums, and 114 kings. Gordon Ashton again carried on the work at this place, under the supervison of Acting Warden Ralph A. Ferrandini.

#### RED RIVER

The weir in Red River was completed on May 15, and the first escapement was counted on May 23, when six king salmon passed upstream. The red-salmon run began on the following day. Counting was continued through August 28, at which time the total escapement consisted of 253,994 red salmon, 1,671 kings, and 673 cohos.

Although the catch exceeded the escapement at Red River in the latter part of July, it was not necessary to close the area at that time, as the difference was too small. However, this district was closed through the remainder of the season after August 21. During the season 95,795 Dolly Varden trout were taken in a trap and destroyed.

Tom Frost, at the beginning of the season, and later Henry B. Looff, had charge of operations at this weir, under the direction of Warden J. Steele Culbertson.

# SITUK RIVER

Construction of the weir in Situk River was completed on June 11, and the first salmon passed through on the following day. Counting was continued through July 21, after which high water prevented accurate observations, and the structure was finally washed out on July 27. The total count for the season was 118,777 red salmon, 2,750 pinks, and 1,290 kings. Axel W. Tveter was in charge of operations at this place, under the direction of Warden William B. Berry.

#### SALMON LIFE HISTORY STUDIES

Studies of the life histories and fluctuations in the abundance of the Pacific salmon in Alaska were continued in 1937 by the staff of the Fisheries Biological Station at Seattle, Wash. The major investigations of the red salmon at Karluk and the pink salmon at Little Port Walter were carried on as formerly. Biological data on the red salmon in the Bristol Bay, Chignik, and Copper River areas were also collected. Daily catch records of the fishing boats operating in Bristol Bay from the inception of the industry up to the present time were compiled during the year.

Studies carried on at Karluk River and Little Port Walter gave further insight into the natural factors that influence the abundance of the salmon. The biological work at Karluk during the past year included studies of the influence of predatory trout on the abundance of the red salmon spawning in the river system. The

cooperative project with the National Canners Association dealing with the biological changes within the pink salmon due to sexual

development was continued at Little Port Walter.

The collection, compilation, and analysis of records of the daily catch of salmon in Alaska by the principal types of fishing apparatus were continued in 1937, and provided information as to the fluctuation in abundance and time of appearance of salmon runs in the various This information is of importance in determining adequate regulations for the conservation of the salmon.

#### OBSERVATIONS ON THE ESCAPEMENT OF SALMON

As in previous years, the size and condition of the salmon runs were closely observed in all districts during the commercial fishing season with a view to determining whether any immediate modifications of the regulations were necessary in order to assure an adequate reservation of broad fish. After the close of the season an inspection was made of representative streams in the various districts. requirement of law that not less than 50 percent of the runs be permitted to escape was fully met in streams where counting weirs were maintained, and there was in general a satisfactory seeding of all

spawning grounds.

Southeast Alaska.—In the Ketchikan district, embracing the southern district and that part of the Clarence Strait district south of Ernest Sound, the run of salmon was slow at the start, but increased later, holding up fairly steady until after the close of the fishing season. and the spawning grounds as a whole were adequately seeded. tically all streams on the east coast of Prince of Wales Island as far north as Kasaan Bay had good escapements. Tolstoi Bay and Thorne Bay likewise had good escapements. Probably the poorest escapement in the district was in the western part of Behm Canal, although Yes Bay had a good showing. The escapement in Boca de Quadra and Smeaton Bay was excellent. Some of the smaller streams had a fair escapement, and a few were poorly seeded. From the number of salmon observed in bays of Annette Island and Gravina Island after the close of the fishing season it was apparent that the spawning grounds in tributary streams would be well seeded.

The stream survey in the Wrangell district and adjacent waters of

Sumner Strait and the northern part of Clarence Strait, while not as thorough as desired, was fairly comprehensive and showed that the escapement in general was rather light, notwithstanding favoring conditions, such as unusually heavy rainfall and consequent high water August 7 and reached their peak 10 days later.

in the streams. For the region as a whole it was a season of small and detached runs. In western waters of Sumner Strait, off the eastern shores of Kuiu Island, sizeable runs of pink salmon began about This locality (including Rocky Pass, Threemile Arm, Seclusion Harbor, and Affleck Canal), together with Totem Bay on the south shore of Kupreanof Island, was the only part of Sumner Strait that had a good run of pinks. the close of the season there was a fair run of pink salmon in Whale A fairly good run of this species occurred also in the Stikine district, reaching its peak during the last 2 weeks of July. The run of pink salmon in streams of Bradfield Canal was unaccountably small, in view of the large escapement there in 1935. There was an excellent run of king salmon in the Stikine district and a good escapement.

This region also had a good run of red salmon. Other red-salmon streams that had good escapements were those tributary to Salmon Bay and Lake Bay. Barrie Creek had a meager escapement of both reds and pinks. The runs of chums and cohos were light throughout

the Wrangell district.

The run of pink salmon was very late on the west coast of Prince of Wales Island, not appearing in any volume until the middle of August, and then the run was irregular. At no time was there a steady run in any locality. Pink salmon began striking into the bays and inlets of the South Prince of Wales Island district about August 29. During the stream examination in September if was found that the run had increased and as a result of the heavy rains the fish immediately entered the streams, assuring a fair escapement of this species. The northern part of Prince of Wales Island, however, including tributaries of Sumner Strait, and streams of Tuxekan Passage, El Capitan Passage, Calder Bay, Sea Otter Sound, and Davidson Inlet, had a very poor escapement of pink salmon, and of other species as well. There was a fair escapement of red salmon in Sarkar Lake, in Klawak Creek, and in various red-salmon streams in the South Prince of Wales Island district. The runs of cohos and chums were very disappointing all along the west coast of Prince of Wales Island.

In the Icy Strait district salmon were not plentiful during the first part of the season; but the run increased gradually, reaching its peak about July 20 and holding up fairly well until the end of the season. In the eastern and western districts there was a poor showing of salmon until August 4 and a good run thereafter until the close of the season. The run in Stephens Passage was one of the heaviest in years. Reports of stream guards indicate that red-salmon streams of these districts were fairly well seeded, and that the pink-salmon escapement was good in some areas and poor in others, being ample in the Icy Strait district as a whole, fair along the west coast of Admiralty Island south of Killisnoo, poor along the coast north of Killisnoo, and satisfactory throughout the eastern district. An excellent seeding was obtained in the mainland streams of Stephens Passage. The escapement of

chums and cohos was about average in all three districts.

The curtailment of commercial fishing because of stormy weather in certain parts of the Yakutat district assured a better than average escapement. There was a fair escapement from a rather light run of king salmon in Alsek River and also a satisfactory escapement of reds and cohos. Good escapements of reds and cohos were also secured in Italio River and Ahraklin River, and of all species in Situk River. The runs and escapements in Lost River and Ankau Inlet were fair, and Humpback Creek had the best escapement of pink salmon it has

had for several years.

Prince William Sound and Copper River region.—The run of pink salmon in Prince William Sound as a whole was unusually late and very light during the commercial fishing season. This was particularly true on the eastern and southern sides, where the run was poor in most localities. On the western side the run began earlier and in some sections held up fairly well until the close of commercial fishing. The best showing in the sound was along the Chenega shore and in the Port Wells area, and the escapement there was good. Because of the generally light run a supplementary order was issued closing Prince William Sound to commercial fishing on August 2, or 3 days earlier

than originally specified. An improvement in the run during the last week of the fishing season gave promise of a fair escapement for the entire district, and one materially larger than in any other recent odd

year.

A larger run of red salmon than usual entered the Copper River, the main run appearing from June 8 to 15. In Bering River the main run was from June 20 to 26. Few fishing boats were engaged in taking fish from the latter run, and stormy weather hampered operations for the first 3 weeks of the fishing season on Copper River. Reports indicated that the escapement of reds and kings in the tributaries of Copper River was the best it had been for several years.

In the Resurrection Bay area red salmon were small and the run was light, somewhat similar to the poor run in 1930. A fair run of cohos began on September 11 and continued until the latter part of the month. Stormy weather prevented fishing during this period,

and as a result there was a good escapement of this species.

Cook Inlet.—In general the runs of all species of salmon in the Cook Inlet area were later than usual, with the possible exception of chums. Few king salmon were in evidence prior to the opening of commercial fishing on May 25, but the run held up well throughout the season, reaching its peak between June 12 and 19. While the catch of king salmon was the largest on record in the district, there was no notable increase over former years in the number of this species observed on the spawning grounds visited, mainly on the Kenai and Kasilof Rivers.

The early run of red salmon was light, but a second run appeared on July 24, much heavier than the first, with the greatest number of fish centered near the mouths of the Kenai and Kasilof Rivers. The latter run continued in fair numbers until several days after the close of the fishing season. An excellent escapement of red salmon was observed on the spawning grounds of the Kenai and Kasilof Rivers, particularly of the latter, where, with the exception of one stream all tributaries were seeded to capacity. A good escapement also entered the Kalgin Island stream. At Fish Creek, Knik Arm, the escapement of red salmon was approximately 75 percent less than in the previous The escapement at English Bay and Chinik Creek was disappointing, particularly that in the latter stream, which was the poorest since improvement was started on the falls at the mouth of the stream in 1926. Prior to that time it was impossible for salmon to ascend these falls, except during a short interval on the higher tides. Since the falls were improved the salmon may enter this stream even during the smallest tides.

The pink-salmon run, while spotted, averaged good for the odd year. In the Port Dick region, where the runs of pinks and chums were heaviest, the escapement was very good. Streams on the outer coast from Point Gore to Port Chatham had a fair seeding. There was also a fair escapement of pinks at Seldovia Bay and Tutka Bay. In other streams south of Anchor Point, including Kachemak Bay, the escape-

ment was light.

Kodiak area.—Enormous runs of pink salmon entered Uganik Bay and Uyak Bay, and this species was abundant also in other parts of the Kodiak area, particularly in Alitak Bay and waters along the east coast of Kodiak Island. A good escapement of pinks was observed in all streams examined at the close of the season. The streams were well supplied with water, and the salmon had no difficulty ascending to

the spawning grounds. Red salmon in the district as a whole were less plentiful than in the previous year, and the runs were irregular. At Olga Bay the escapement of this species was the best for several years, the escapement at Karluk was fair, and that at Red River was below the average. The runs and escapements of other species were fair.

Chignik.—The run of red salmon in Chignik River was very light throughout the season and the required 50-percent escapement was obtained only by additional curtailment of commercial fishing. The run of pink salmon was unusually good for this district and was the largest since the season of 1926. The runs and escapements of chum and king salmon were a little above the average, and the run and

escapement of cohos was very light.

Alaska Peninsula.—As in the previous year, the heaviest run of red salmon on the south side of the Alaska Peninsula in 1937 occurred in the last 2 weeks of June, while on the north side of the peninsula the peak of the run was about the middle of July. Red salmon in this district were never abundant throughout the season, and the runs and escapements of cohos and kings were also small. There was an exceptionally heavy odd-year run of pink salmon, which continued strong after the close of the fishing season, assuring an adequate

seeding of the spawning beds. The run of chums was good.

Bristol Bay.—The run of red salmon in Bristol Bay as a whole was light at the beginning of the season but later developed into very good volume. The Nushagak district had the best run in nearly two decades, the fish arriving in large numbers on June 29 and continuing until the middle of July, when there was a tapering off of the larger schools. In the Kvichak-Naknek district the main run occurred after July 10, and the peak of the run in the Egegik district was from July 16 to 20. The season at Ugashik was still later, with few fish until July 20, after which there was a heavy run, reaching the peak of abundance on July 22, and continuing in good numbers after the close of the season.

Comprehensive surveys, partly by airplane, were made of the various districts after the close of the fishing season. Excellent escapements were observed in the Wood River and Tikchik Lakes systems, in the Lake Clark area of the Kvichak watershed, and in Lake Brooks and Naknek Lake of the Naknek watershed. Streams tributary to Ugashik Lakes were only lightly populated with red salmon, which is normal for this area, and a number of streams in the Egegik district appeared to be seeded to but 25 percent capacity. The seeding of the spawning beds of the Bristol Bay area as a whole, however, was very satisfactory.

#### GENERAL STATISTICS OF THE FISHERIES

The total number of persons engaged in the fisheries of Alaska in 1937 was 30,331, or 52 less than in 1936. Fishery products were valued at \$51,743,220, an increase of \$1,287,948, or about 3 percent, over the value in the preceding year. Of the total amount, 90 percent represented the value of salmon products; 5.6 percent, herring; 1.9 percent, halibut; and 2.5 percent, the value of all other fishery products.

1 These figures represent the value of the manufactured product. It is estimated that the value of the catch, exclusive of whales, to the fishermen was approximately \$14,238,000. The round weight of this salmon each landed by the fishermen was approximately \$83,384,000 pounds, and the corresponding figure for herring was approximately 206,446,000 pounds. The cod figures given above do not include the offshore catch from waters adjacent to Alaska, which amounted to 3,776,983 pounds of dry-salted cod and 18,940 pounds of tongues, having a total value of \$188,611, landed at ports of the Pacific Coast States.

#### SALMON

Although the runs of salmon in Alaska as a whole were lighter in 1937 than in the previous year, they were better than average, particularly for an odd year, and the catch was the third highest on record, having been surpassed only in 1936 and 1934. The catch of pink salmon showed a marked decline in southeast and western Alaska, but was the largest ever obtained in the central district, chiefly as a result of very heavy runs in the Kodiak and Ikatan-Shumagin areas, which more than offset the decrease in Prince William Sound. It should be noted, however, that the individual fish were of smaller size than in 1936, and whereas there was a substantial gain in the number of pinks taken, the pack for the central district was somewhat less than that of the previous year. The runs of red salmon were good in southeast and western Alaska and light in most parts of central Alaska. The catch of cohos was below average, that of chums was fair, and the catch of king salmon was the largest ever taken in Alaska.

The total catch of salmon decreased about 16 percent from that for 1936. By districts, the decrease was about 29 percent in southeast Alaska, about 3 percent in central, and 4 percent in western

Alaska.

The apparatus operated in Alaska as a whole in 1937 varied but little from that of the previous year, the number of traps remaining the same and the number of fathoms of seines and gill nets showing less than 1 percent difference.

#### CATCH AND APPARATUS

The total number of seines used in the salmon industry in 1937 was 995, of which 786 were purse seines and 209 beach seines. The purse seines aggregated 118,826 fathoms of webbing and the beach seines 20,119 fathoms. The number of gill nets used was 4,115, having a total length of 296,011 fathoms. There were 170 driven

and 283 floating traps—a total of 453.

Southeastern Alaska was accredited with 532 seines, or a total of 90,576 fathoms, a decrease of 20 seines and 5,509 fathoms of webbing from the number used in 1936; also with 384 gill nets, aggregating 24,960 fathoms, an increase of 25 nets but a decrease of 1,370 fathoms of webbing; and with 32 driven and 252 floating traps, an increase of 2 driven traps and a decrease of 2 floating traps, as compared with the number operated in 1936.

Corresponding figures for central Alaska show 455 seines, or 46,169 fathoms, as compared with 396 seines, or 41,749 fathoms, in 1936; 1,537 gill nets, or 99,570 fathoms, as compared with 1,522 gill nets, or 85,690 fathoms, in 1936; and 138 driven and 31 floating traps, as

compared with 139 driven and 30 floating traps in 1936.

In western Alaska 8 seines, or 2,200 fathoms of webbing, were used, an increase of 4 seines and 1,200 fathoms of webbing over the number operated in 1936. There were 2,194 gill nets used, or an aggregate of 171,481 fathoms, a decrease of 136 nets and 13,072 fathoms of webbing. No traps were operated in this district.

Seines caught 28 percent of the salmon taken in 1937, gill nets 24 percent, and traps 46 percent, while lines and wheels took the remain-

ing 2 percent.

Percentage of salmon caught in each Alaska district, by principal forms of apparatus

	Southeas	t Alaska	Central	Alaska	Western	Alaska

Lines Wheels	2	3			2	1

The total catch of salmon in 1937 was 109,114,923, a decrease of 20,211,280, or nearly 16 percent, from the number taken in 1936. There was a decrease of 18,048,736 in southeast, 1,121,180 in central, and 1,041,364 in western Alaska. By species, the catch of cohos decreased 806,538; chums, 3,121,124; pinks, 11,809,300; and reds, 4,651,984; while the catch of kings increased 177,666.

#### CANNING

#### CHANGES IN CANNERIES

Comparatively few changes in operation or management of the salmon canneries in Alaska took place in 1937. In southeast Alaska the Burnett Inlet plant, formerly operated by the Alaska Pacific Fisheries, but idle since 1930, was purchased and operated by a new corporation, the Burnett Inlet Salmon Co. The Kasaan cannery of the Pacific American Fisheries, taken over from the Northwestern Fisheries Co. and idle since 1930, was also reopened.

During the fall of 1936 and the spring of 1937 the Nakat Packing Corporation replaced its cannery buildings at Waterfall and now has there one of the finest canneries in southeast Alaska. The new structures include a cannery building with power-house and machine shop, a warehouse, store and office, carpenter shop, mess and bunkhouse, main dock, and walks and runways. The cost of construction

of this plant was approximately \$145,000.

In central Alaska the plant at Resurrection Bay formerly known as the Seward Fisheries, Inc., was reopened and operated by Hagen & Co., after having been closed for 2 years. The North Pacific Sea Foods Co. completed and operated a new cannery at Swanport, about one-half mile from the old cannery at Fort Liscum, which was destroyed by fire in the fall of 1936. The Kadiak Fisheries Co. leased the cannery of Shelikof Packing Co. at Zachar Bay and operated it in addition to the plants at Kodiak and Shearwater Bay. The plant of the Kustatan Packing Co. at Anchorage was purchased and operated by the General Fish Co., Inc. The Northern Light Packing Co.'s plant at Mountain Slough, last operated in 1932, was taken over and operated by L. Utness.

The Naknek cannery formerly owned by Northwestern Fisheries Co. and now belonging to the Pacific American Fisheries, Inc., which had been closed down since 1931, was again put in operation. This plant is located on the north shore of the Naknek River and is known as the Nornek unit of Pacific American Fisheries, Inc. The company's Naknek plant is farther up the Naknek River and on the south shore. Before the beginning of the fishing season the Bristol Bay Packing Co. had completed one of the two new canneries which are to replace the buildings lost by fire in 1936. The plant was operated during the season with six lines of machinery. When the other can-

nery is completed, each will be a five-line plant.

Joint operating arrangements were again carried on by a number of companies having canneries in the same district, resulting in the closure of several additional plants in the 1937 season.

## NEW CANNERIES

There were two new floating plants in the Kodiak district—the motor vessel Commander (282 tons), operated by Suryan's, Inc., in Moser Bay, and a large scow operated by Frank McConaghy Co., Inc., at Zachar Bay. Other new canneries were the Northern Fisheries, Inc., at Ketchikan, and the Phillips Canning Corporation at Valdez. Although the latter produced a small hand-packed output in each of the years from 1934 to 1936, inclusive, it has not been included heretofore in the list of canneries. The Gulf Packing Co., at Cordova,

and Kayler-Otness, Inc., at Petersburg—both engaged in the packing of crab meat for several years—added substantial outputs of canned salmon to their production this season and are included for the first time in the list of salmon canneries.

The Alaskan Glacier Sea Food Co. put up a small pack of canned salmon at its crab cannery at Hoonah, but this plant has not been

included in the list of salmon canneries.

#### CANNERIES NOT OPERATED

Fifteen plants that had canned salmon in the previous year were not operated in 1937. Four of these were in southeast Alaska, eight in the central district, and three in western Alaska. In southeast Alaska those closed for the year were the Lane Bros. cannery at Moira Sound, the Seaport Salmon Co. at Ketchikan, and the plant of Demmert Packing Co. at Klawak which had been leased to Robert Lindenberger and operated as the Klawak cannery of the Ocean Packing Co. in 1936. The Hidden Inlet plant of the Nakat Packing Corporation was destroyed by fire in May 1937, and the salmon taken in its traps during the season were packed at the company's Union Bay and Waterfall canneries.

In central Alaska the plant of the Surf Canneries, Inc., at Kukak Bay, which burned down in September 1936, was not rebuilt. The plant of the Shepard Point Packing Co. at Port Ashton was engaged solely in the manufacture of herring oil and meal. Other canneries in the central district that were closed for the 1937 season were the Alaska Pacific Salmon Co. at Drier Bay, the Aleutian Fishing & Packing Co. at Sand Point, the plant of Herbert T. Domenici at Uyak, the Glacier Sea Foods Co. at Cordova, the Ninilchik Packing Co. at

Ninilchik, and the Premier Salmon Co. at Stevens Creek.

The Lockanok and Nushagak plants of Libby, McNeill & Libby on Bristol Bay were closed, the company having consolidated operations at its four other plants in that area. The Pacific American Fisheries cannery at Nushagak, which was leased to Lowe Trading Co. in 1936, also was closed during the season.

The cannery of Strand-Jensen Fisheries Co. at Cordova has been dropped from the list of idle plants, as it has been dismantled and is

not likely to be operated again.

The following canneries were closed during the year but may be reopened:

Southeast Alaska:

## TOTAL CANNERIES OPERATED

One hundred and thirteen canneries were operated in Alaska in 1937—46 in southeast, 44 in central, and 23 in western Alaska—which is the same number as in the previous year for southeast Alaska, and a decrease of 3 for the central and 1 for the western district, a net decrease of 4 plants from the number operated in 1936. The floating canneries *International*, of the International Packing Co., and *Memnon*, of the Columbia River Packers Association, Inc., were operated in both central and western Alaska, but each is credited to but one district, the former to central and the latter to western Alaska.

Primarily a crab cannery.
 Traps only were operated, the fish being packed at other canneries.
 Because this plant is in the Karluk district, the location has been shown as "Karluk" for many years.
 Canning operations originally carried on at the Karluk site were transferred to Larsen Bay in 1911. To avoid misunderstanding, the specific location, rather than the district, will be shown hereafter.

## LOSSES AND DISASTERS

One of the most serious disasters in the Alaska fisheries in many years occurred toward the end of September when the purse seiner *Limit*, of Storfold & Grondahl Packing Co. foundered in a gale in Chatham Strait and was lost with its entire crew of eight men.

The major property loss in the Alaska fisheries in 1937 was the destruction of the Hidden Inlet plant of the Nakat Packing Corporation by fire on May 26, before the fishing season started. The loss of buildings, equipment, fishing apparatus, boats, and supplies amounted to \$268,603. Other losses by fire in southeast Alaska included the herring plant of the Red Bluff Fisheries in August and the crab canneries of Kayler-Otness, Inc., at Petersburg, and the

Salt Sea Fisheries, at Tenakee, both of which burned down in November. The total reported losses in the fisheries industry in southeast Alaska amounted to \$376,240.

Operators in central Alaska reported property losses totaling \$44,061, the principal item being the vessel North Dakota, which, with

fishing apparatus, was valued at \$9,900.

In western Alaska the herring saltery of the Golovin Bay Packing Co., on Golovin Bay, which had not been operated for two seasons, was burned down about the middle of October, with a loss amounting to \$21,250. Other reported losses, consisting chiefly of boats and

gear, brought the total for the western district to \$37,742.

Twenty-one lives were lost during the year—11 in southeast, 6 in central, and 4 in western Alaska. In the southeastern district 8 fishermen and 1 transporter were drowned, 1 fisherman met death by accident, and 1 shoresman died of disease. Two shoresmen and 1 transporter in central Alaska were killed in accidents, 2 shoresmen died of disease, and 1 shoresman was drowned. In western Alaska 2 fishermen and 2 shoresmen died of disease.

#### STATISTICS

One hundred and thirteen canneries were operated in Alaska in 1937, or four less than in the previous year. Employment was given to 24,865 persons, as compared with 25,221 in 1936, a decrease of 356. White employees increased 311; Filipinos, 84; Mexicans, 8; Negroes, 13; and miscellaneous (Koreans, Chileans, Peruvians, etc.), 40; while natives decreased 412; Chinese, 105; Japanese, 242; Kanakas, 23; and Puerto Ricans, 30.

The total pack of canned salmon was 6,669,665 cases, valued at \$44,547,769. This is a decrease of 21 percent in quantity and less than one-half of 1 percent in value from the production in 1936, when the pack amounted to 8,437,603 cases, valued at \$44,751,633. Average prices of all species were considerably higher in 1937 than in the previous year, reflecting increased operating costs as a result

of higher wages and increased costs of materials.

The output of canned salmon in southeast Alaska decreased from 4,076,717 cases in 1936 to 2,933,896 cases in 1937, or 28 percent; in central Alaska the decline was from 2,869,681 cases to 2,216,359 cases, or about 23 percent; while in western Alaska the output increased from 1,491,205 cases to 1,519,410 cases, or about 2 percent. By species, in Alaska as a whole, the pack of cohos declined from 222,300 cases in 1936 to 137,317 cases in 1937, or 38 percent; chums, from 1,101,083 cases to 730,832 cases, or about 34 percent; pinks, from 4,559,794 cases to 3,625,379 cases, or 20 percent; and reds from 2,502,542 cases to 2,106,669 cases, or 16 percent; while the pack of kings increased from 51,884 cases to 69,468 cases, or 34 percent.

Details are included in the following tables to show comparison of the 1937 pack with the average for the 5 preceding years, 1932 to 1936, by cases of each species and by districts. Pinks, kings, and reds show gains of about 14 percent, 38 percent, and 3 percent, respectively, over the 5-year average, while cohos declined 28 percent and chums 12 percent. By districts, the pack in 1937 increased approximately 10 percent over the 5-year average in central Alaska and 13 percent in the western district, while in southeast Alaska there was a

decrease of less than 1 percent, making a net increase of nearly 6 percent over the 5-year average for all of Alaska.

## PACK IN CERTAIN DISTRICTS

Statistics of the salmon pack are again presented for subdivisions of the three main districts of Alaska, and comparison is made with similar statistics for 1936. Where the pack at a given cannery is made up of fish from more than one district, as in the case of that at certain Cordova canneries packing fish caught both in Prince William Sound and in the Copper River area or at various plants in southeastern Alaska which draw for their supply on the catch of more than one district, due segregation has been made in order to credit each district with the pack from salmon caught therein. These districts are described as follows:

#### WESTERN ALASKA

Bristol Bay.—The Bering Sea shore, east and north of the Ugashik River.

Port Moller and Herendeen Bay.—Port Moller, Herendeen Bay, and Nelson Lagoon.

#### CENTRAL ALASKA

Ikatan-Shumagin Islands.-False Pass, Ikatan Bay, King Cove, and the Shumagin Islands.

Chignik.—Mainland shore from Castle Cape to Cape Kunmik. Kodiak-Afognak Islands.—Kodiak, Spruce, and Raspberry Islands.

Cook Inlet.—The shores of Cook Inlet.

Prince William Sound.—Resurrection Bay to Point Whitshed.

Copper and Bering Rivers.—Point Whitshed to Bering River.

#### SOUTHEASTERN ALASKA

Yakutat and Dry Bay.—Yakutat Bay to and including Dry Bay.

Icy Strait-Lynn Canal.—West coast of Baranof and Chichagof Islands, the shores of Cross Sound, Icy Strait, Lynn Canal, and Stephens Passage, south to Taku Harbor.

Chatham Strait-Frederick Sound.—Both shores of Chatham Strait and its bays from Point Augusta to Cape Ommaney, and through Frederick Sound and its bays northward to Taku Harbor, including Kake.

Sumner Strait-Dixon Entrance.—Southward from Petersburg and eastward from Port Beauclerc to Cape Chacon and Dixon Entrance, and including all shores along the mainland and intervening islands from the Stikine River to Portland Canal.

West coast, Prince of Wales Island.—Territory west and south of a line from

Cape Chacon to Point Baker and Cape Ommaney.

#### MILD CURING

The production of mild-cured salmon in Alaska in 1937 increased substantially over that for the previous year and was the largest since 1927. Except for a limited amount prepared by two operators on the Yukon River, the entire output was put up in southeast Alaska.

The registration of trolling boats in southeast Alaska by the Bureau was again incomplete; when this work was undertaken in May, many

of the boats were not fishing, owing to the low price of fish, and it was difficult to obtain the required information. The figures published

herewith, therefore, are partly estimated.

Seventeen plants were operated and 1,605 persons were employed, as compared with 21 plants and 1,513 persons in 1936. Mild-curing operations were carried on also by a considerable number of plants engaged primarily in other branches of the fisheries.

The total output of mild-cured salmon was 5,721,600 pounds, valued at \$1,064,344, an increase of 1,238,400 pounds in quantity and \$265,780

in value over the output of the previous year.

#### PICKLING

Although somewhat short of that of the 2 previous years, the production of pickled salmon in Alaska in 1937 compared favorably with the general average. About 60 percent of the output was prepared in the western district, chiefly in Bristol Bay; 38 percent was from central Alaska, where the Shumagin Islands region and Cook Inlet were the chief producing centers; and the remaining 2 percent was from southeast Alaska. A considerable number of small outfits engaged in this industry for part of the season, and some pickled salmon was produced in connection with salmon canning or other fisheries.

One hundred and twenty-one persons were employed—an increase of 15 over the number reported for 1936. The total output was 765,396 pounds, valued at \$100,550, as compared with 872,915 pounds, valued at \$96,510, in the previous year.

#### FRESH SALMON

Twenty-three firms in southeast Alaska reported an output of fresh salmon in 1937. This production was largely incidental to other branches of the fisheries. Four operators whose chief product was fresh salmon gave employment to 10 white shoresmen. The total products amounted to 3,421,129 pounds, valued at \$292,316, as compared with 4,690,507 pounds, valued at \$369,442, in 1936—a decrease of 27 percent in quantity and 21 percent in value.

## Products of the Alaska fresh-salmon industry in 1937

Coho, or silver	539, 022 14, 439 2, 867, 668	\$43, 047 608 248, 661
Total	3, 421, 129	292, 316

### FREEZING

As in the previous year, the freezing of salmon in Alaska in 1937 was carried on only in the southeastern district and was largely incidental to mild curing. Ninety-eight white shoresmen, not shown elsewhere, are credited to the industry. The total output was 5,344,666 pounds, valued at \$431,614, as compared with 5,574,914 pounds, valued at \$374,330, in 1936—a decrease of 4 percent in quantity, but an increase of 15 percent in value. These figures do not include salmon frozen for use as bait in the halibut fishery.

## Products of the Alaska frozen-salmon industry in 1937

DRY-SALTED, DRIED, AND OTHER MISCELLANEOUS SALMON PRODUCTS

In southeast Alaska a pack of canned kippered salmon was prepared by one of the salmon canneries at Ketchikan, the total production amounting to 254 cases of kings and 60 cases of chums, 48 half-pound cans to the case, valued at \$1,524 and \$270, repectively. In this district, also, there were produced 59,750 pounds of frozen salmon, valued at \$634, for use as bait in the halibut fishery. In central Alaska one outfit on Cook Inlet prepared 11,200 pounds of dry-salted king salmon valued at \$1,800 and 525 pounds of dry-salted red salmon valued at \$100.

In the fishery of the Yukon, Tanana, and Kuskokwim Rivers, which is carried on principally by natives, 1,148,000 pounds of dried chum salmon were prepared, valued at \$79,900. Ten whites and 616 natives engaged in the fishery, and the apparatus used consisted of 249 wheels, 388 gill nets of 5,861 fathoms, 2 dories, and 50 rowboats and skiffs.

#### BYPRODUCTS

Salmon meal and oil were prepared at a byproducts plant in southeast Alaska, which gave employment to 24 white shoresmen, and at a salmon cannery on Larsen Bay, in the central district, in connection

with the canning operations.

The total production in 1937 was 1,972,000 pounds of fertilizer, valued at \$29,151, and 78,100 gallons of oil, valued at \$23,956, as compared with 1,554,000 pounds of fertilizer, valued at \$24,579, and 45,435 gallons of oil, valued at \$13,984, in 1936—an increase of about 27 percent in the output of fertilizer and 72 percent in the output of oil.

#### HERRING

Outstanding features of the herring industry of Alaska in 1937 were a sharp curtailment in the production of Scotch-cured herring and a marked expansion in the manufacture of meal and oil, resulting in an all-time record in the total volume of herring products in the Territory.

Only negligible quantities of Scotch-cured herring were prepared in southeast and western Alaska, and the output of this product in the central district was far below normal. Unfavorable market conditions, rather than a scarcity of herring suitable for curing, were primarily responsible for the decline. Most of the plants in southeast Alaska and on Prince William Sound undertook no saltery operations whatever, their entire attention being devoted to the reduction business.

Apparently the only district affected by a shortage of herring was western Alaska, where there was a failure of the runs virtually throughout the season in waters of Dutch Harbor and Akutan Bay in which gill-net fishing is conducted. As in the previous year, there was no production of herring in Golovin Bay. The plant of the Golovin Bay Packing Co. was destroyed by fire in October, with a loss of \$21,250.

A good early showing of herring appeared in the Prince William Sound area, forcing some of the plants to put their boats on limit for a time. In the Kodiak area the runs began later and the fish were of excellent quality. About 9,900 barrels of herring from this district

were transferred to plants on Prince William Sound.

Of the total output of Scotch-cured herring, less than 75,000 pounds came from southeast Alaska, and approximately 30,000 pounds from the Aleutian Islands area. The Kodiak area produced 1,467,290 pounds and the Prince William Sound area 528,125 pounds, or 70 per-

cent and 25 percent, respectively, of the entire output.

There were 14,167,860 pounds of meal and 2,173,460 gallons of oil produced in the Prince William Sound area, or about 38 percent and 39 percent, respectively, of the total production of meal and oil in Alaska. In the Kodiak area 7,565,066 pounds of meal and 1,421,841 gallons of oil were prepared, or 20 percent and 26 percent, respectively, of the entire output. The proportionately larger yield of oil than of meal in the latter district may be accounted for by the fact that herring there were unusually fat. Forty-two percent of the total output of meal and 35 percent of the oil came from southeast Alaska.

Twenty-two concerns handled herring in southeast Alaska, including six cold-storage plants that froze herring for bait and seven outfits engaged solely in the production of bait herring. Three plants in southeast Alaska that had been closed in 1936 were reopened, among them the plant formerly leased by Richmond Fisheries, Inc., at Red Bluff Bay, which was taken over by a new organization, Red Bluff Bay Fisheries, Inc. This plant was destroyed by fire on August 13, 1937.

The following companies operated in the district:

Chatham Strait Fish Co\_\_\_\_\_\_\_ New Port Walter
Northwestern Herring Co\_\_\_\_\_\_ Port Conclusion.
Port Herbert Packing Co\_\_\_\_\_\_ Port Herbert.
Red Bluff Bay Fisheries, Inc\_\_\_\_\_\_ Red Bluff Bay.

In central Alaska 10 plants manufactured herring meal and oil, the same number as in the previous year. Five of these plants prepared also the bulk of the Territory's output of Scotch-cured herring. In addition, a small quantity of Scotch-cured herring was produced in connection with salmon pickling in the Kodiak district. The plant of Johnson Fisheries Co. on Thumb Bay was purchased by the Oceanic Fisheries Co. and operated as the Port Oceanic plant by the new owner. The principal operators in the central district were as follows:

Saltery and reduction plants:

Apex Fish Co.	Port Wakefield.	
Chatham Strait Fish Co	Crab Bay.	
Oceanic Fisheries Co., Inc.		Port
	Vita.	
San Juan Fishing & Packing Co	Port San Juan.	
Reduction plants:		
Evans Bay Packing Co., Inc.	Port Benny.	
George Hogg & Co	Blue Fox Bay.	
Perfection Fisheries, Inc	Thumb Bay.	
Shepard Point Packing Co		

The only output reported from western Alaska was a limited amount of Scotch-cured herring and a small quantity of bloater stock by the following operators:

	Campbell &	Dougal	Dutch Harbor.
٠	Hoveland &	Nesshaug	Do.

Studies concerning the life history and fluctuations in the abundance of the herring populations in Alaska were continued by Edwin H. Dahlgren and an assistant. These studies were carried on in the Chatham Strait fishing area of southeast Alaska and in the Prince William Sound and Kodiak areas of central Alaska.

## STATISTICAL SUMMARY

There were 988 persons engaged in the herring industry in 1937, as compared with 1,111 in 1936. The number of plants decreased from 27 to 20. Products of the fishery were valued at \$2,891,854, an increase of \$816,222, or about 39 percent over 1936, when the total value was \$2,075,632. Scotch-cured herring decreased from 11,413,225 pounds, valued at \$538,211, to 2,098,040 pounds, valued at \$107,968, or about 82 percent in quantity and 80 percent in value. Herring for bait decreased from 6,298,105 pounds, valued at \$57,200, to 5,238,172 pounds, valued at \$48,816, or about 17 percent in quantity and 15 percent in value. Meal increased about 33 percent in quantity and about 21 percent in value, and oil increased 49 percent in quantity and 122 percent in value.

## HALIBUT

The halibut fleet again operated under a voluntary productioncontrol program, the purpose of which is to equalize deliveries insofar as possible during the season, thus tending to promote more favorable market conditions. Except for a few minor changes, the control program in effect in 1937 was the same as that for the previous year. Some of the vessels began fishing on March 16, some a week later, and the remainder on March 26. Catch limits per man per trip were established, depending upon the area in which fishing was conducted and on the port of landing; and vessels were required to stay in port

10 days between trips, which period was lengthened if trip quotas were

exceeded, and shortened if the trip limit was not reached.

Operations were governed also by regulations of the International Fisheries Commission. These regulations were modified somewhat under the provisions of the new halibut treaty between the United States and Canada which became effective on July 28, 1937. For the first time fishermen were permitted to retain halibut taken incidentally in fishing for other species in a closed halibut area. The retention of such halibut, however, was restricted to vessels using set lines and operating under specific permit, and the proportion of halibut in the catch taken and sold was limited to 1 pound of halibut to 7 pounds of other species, exclusive of salmon. Another modification of the regulations involved prescribing the final date on which vessels could leave port for the fishing banks, instead of specifying the closing date of the season. Catch quotas, which were the same in 1937 as in the previous year, were reached earlier than ever before, and the fishing season closed on July 28 in area 2 and on October 19 in area 3. The final date of departure from port for fishing in the latter area was September 29. Closing dates in areas 1 and 4 were the same as in areas 2 and 3, respectively.

The sale of fish livers for pharmaceutical purposes has become well established as an important source of revenue in the halibut industry. Halibut livers brought a price of 50 cents a pound in 1937, or more than four times the price paid in 1932 when this product was begin-

ning to find a profitable market.

Biological studies of the halibut and the collection and analysis of statistical data of the fishery were continued by the International Fisheries Commission under the direction of Dr. W. F. Thompson.

### STATISTICAL SUMMARY

Six hundred and ninety-seven persons were employed in the Alaska halibut fishery in 1937—an increase of 103 over the number reported for the preceding year; and products, exclusive of livers, amounted to 13,281,681 pounds, valued at \$931,629. This production represents the total fares of the Alaska halibut fleet, which comprises all American vessels landing more than one-half of their catch in Alaska or British Columbia ports rather than in the States. Landings of halibut, exclusive of livers, in Alaska totaled 8,705,204 pounds valued at \$557,911, which include 3,000 pounds, valued at \$190, landed by Canadian vessels. In 1936 the landings of the Alaska fleet were 13,566,340 pounds, valued at \$889,454, and landings in Alaska amounted to 8,658,774 pounds, valued at \$507,484. Fares of the Alaska fleet in 1937, therefore, decreased 2 percent in quantity but increased about 5 percent in value over 1936. The landings in Alaska ports in 1937 increased about 1 percent in quantity and 10 percent in value over the preceding year.

The amount of halibut livers landed by the Alaska fleet was not reported, but it was stated that there were altogether about 953,000 pounds of halibut, sablefish, "lingcod," and rockfish livers, valued at about \$449,000, landed at Alaska and Pacific coast ports during 1937 by American vessels, as compared with 997,000 pounds, valued at \$448,000, landed by American vessels in 1936. The estimated amount of halibut livers landed in Alaska was 146,000 pounds, valued at

\$73,000.

These statistics were compiled from data collected by the International Fisheries Commission and by agents of the Bureau.

Persons engaged, wages paid, and operating units, Alaska halibut industry, 1937

#### COD

Cod fishing from shore stations in Alaska is carried on only in a small way, chiefly by independent fishermen in the Shumagin Islands region and in the vicinity of Unalaska. Twenty-six whites and one native were engaged in the industry in 1937, and products amounted to 140,774 pounds of dry-salted cod, valued at \$5,189; 40,510 pounds of pickled cod, valued at \$2,136; and 22,043 pounds of stockfish, valued at \$3,013—a total of 203,327 pounds, valued at \$10,338, as compared with 249,331 pounds, valued at \$11,881, in 1936.

There were four sailing vessels in the Bering Sea fleet, the products of which are not included in the Alaska fisheries output because the vessels operate from, and land their fares in, ports of the Pacific Coast States. The vessels operated were the Sophie Christenson (570 tons), of the Pacific Coast Codfish Co.; the Wawona (413 tons), of the Robinson Fisheries Co.; and the Louise (328 tons) and William H. Smith (496 tons), of the Union Fish Co. The only one of the fleet engaged in the industry in the previous year that was not sent north in 1937 was the Azalea, of the Robinson Fisheries Co.

Products of the offshore fishery were 3,776,983 pounds of dry-salted cod, valued at \$186,996, and 18,940 pounds of tongues, valued at \$1,615—a total of 3,795,923 pounds, valued at \$188,611, as compared with 3,891,307 pounds, valued at \$194,897, in 1936. The off-

shore fishery employed 165 persons, or 29 less than in the previous year. One fisherman lost his life by drowning.

#### WHALES

The two plants of the American Pacific Whaling Co. in Alaska—one at Port Hobron and one at Akutan—were again operated, each having three steamers engaged in the taking of whales. After the close of operations at the former station, two of its whaling vessels finished the season at Akutan. Employment was given to 222 persons.

of whom 203 were whites and 19 natives.

This was the first year of operation under the international treaty for the regulation of whaling, the act of May 1, 1936, giving effect thereto, and the joint regulations of the Secretary of the Treasury and the Secretary of Commerce issued on October 9, 1936. The required whaling licenses were obtained for the processing plants at a fee of \$1,000 each, and \$250 was paid for every vessel in excess of two engaged in the taking of whales in connection with each plant. An officer of the Coast Guard was detailed to each plant to enforce the provisions of the Whaling Act and regulations. Biological information with regard to each whale taken and other statistical data were submitted for communication to the International Bureau for Whaling Statistics at Oslo, in accordance with articles 10 and 11 of the convention.

There were 376 whales taken in 1937, consisting of 1 sei whale, and 170 finback, 104 humpback, 45 sulphur bottom, and 56 sperm whales.

Revised figures for 1936 show a total catch of 372 whales, instead of 385, the original report of the Port Hobron station having included by mistake 13 embryo whales, of which 2 were finback and 11 humpback. The total catch in 1937, therefore, represents an increase of 4 whales over the number taken in the previous year.

Products in 1937 amounted to 715,150 gallons of body oil, valued at \$400,484; 168,250 gallons of sperm oil, valued at \$45,832; 770 tons of fertilizer from meat, valued at \$25,410; and 435 tons of bone fertilizer, valued at \$7,395—a total value of \$479,121, as compared with

\$334,461 in 1936.

## CLAMS

In the Prince William Sound-Copper River region four plants engaged in the production of canned clams in 1937, or three less than in the previous year. Operations were again facilitated by exceptionally favorable weather, both in the spring and fall seasons. The bulk of the pack was put up during the period from April 13 to May 10. Although the regulations for 1937 had been modified to permit a catch of 1,040,000 pounds of clams, round weight, in the first half of the year, as compared with 920,000 pounds formerly, the catch limit was reached by May 10, and operations were discontinued until the fall season opened on August 16. No change had been made in the fall quota of 280,000 pounds, and that limit was reached after 10 days' digging.

A further study of the age composition of the commercial catch of razor clams was made by Paul E. Thompson, special warden engaged in the clam patrol in the above district. More than 98 percent of the clams taken in 1937 were mature, and about 63 percent had spawned more than once. The average catch per man per tide, based upon

operations of 5 experienced diggers, was 348 pounds, as compared with 306 pounds in 1936 and 226 pounds in 1935. These figures indicate the satisfactory condition of the clam beds, as well as the generally favorable weather that prevailed during the period in which most of the clams were taken in the last 2 years.

Very little canning of clams was done outside the Prince William Sound-Copper River region in 1937. Small packs of butter clams were prepared at two plants in southeast Alaska and by an operator on Cook Inlet, and a few cases of clams also were produced in the

Kodiak area. The Cook Inlet output was used locally.

Practically all clam-canning operations were in conjunction with other branches of the fisheries. The following operators handled clams during the season: Alaskan Glacier Sea Food Co., Hoonah; Salt Sea Fisheries, Tenakee; W. R. Gilbert Co. Inc., Point Whitshed; Pioneer Canneries, Inc., Cordova; Sandvik Hand Cannery, Uganik Village; Scotty's Packing Co., Mummy Island; S. E. Smith Packing Co., Hartney Point; and O. G. Tiede, Anchorage.

There were 384 persons employed, of whom 326 were whites, 45 natives, and 13 Filipinos. The total production amounted to 31,800 cases, containing 816,942 pounds (804,078 pounds of razor clams, and 12,864 pounds of butter clams), valued at \$240,392. This is an increase of about 5 percent in quantity and 19 percent in value, as compared with the output for 1936, when clam products amounted to 780,264 pounds, valued at \$201,887.

Products of Alaska clam industry in 1937

#### SHRIMP

In addition to the three plants that have been engaged in the industry for a number of years in southeast Alaska, Kayler-Otness (Inc.) entered the shrimp business in 1937 with the establishment of a shrimp-packing department in its crab cannery, located in part of the wharf building of the Trading Union Co. at Petersburg. Operations of the latter plant were terminated for the season when the building caught fire on November 22 and was destroyed. At Cordova the Alaskan Glacier Sea Food Co. handled a small quantity of shrimp in connection with its crab-packing operations. A part of the output of shrimp there was canned.

There were 194 persons engaged in the industry, of whom 27 were whites, 105 natives, 2 Chinese, 28 Japanese, 29 Filipinos, and 3 Mexicans. Products consisted of 453,744 pounds of cold-packed shrimp meat, valued at \$161,679; 6,567 pounds of frozen shrimp meat, valued at \$2,627; 26 pounds of fresh shrimp meat, valued at \$10; 2,160 pounds of fresh shrimp in the shell, valued at \$321; and 37 cases, or 888 pounds, of canned shrimp meat, valued at \$296—a total of 463,385 pounds, valued at \$164,933. Comparable figures for 1936 show a production of 478,749 pounds, valued at \$162,274.

## SHRIMP-PICKING MACHINE

The Alaskan Glacier Sea Food Co., of Petersburg, started operations in midsummer with a shrimp-picking machine, invented and perfected after 10 years experimenting by V. Bottker in cooperation with Earl N. Ohmer, owner of the sea-food company. About 200 shrimp a minute are handled by the machine, and more of the meat is removed than by the hand process. The machine also handles smaller shrimp than can be picked by hand. The operation is described in the November 1937 Pacific Fisherman, as follows:

Shrimp are fed to the machine automatically through a hopper. As they pass along a belt leading from the hopper they strike a brush that points them tail first between two horizontal disks, which line them on the center of the feed belt. The feed belt carries them between two short parallel rubber belts operating on horizontal disks, which sets the shrimp back up on edge and inserts the bottom of their tails between two lower parallel rubber belts. These belts grip the shrimp and carry them between two small revolving horizontal disks fitted with teeth which engage the bottom of the shrimp shell and extend it slightly to each side. The shrimp then strike a perpendicular revolving toothed disk that tears the shell from the meat. The belt carries the meat through jets of water under high pressure and under a revolving brush, then to a receiver. The disk that removes the shell carries the shell around to a bar and a jet of water, which removes the shell and drops it into a waste receiver. Each machine is individually powered with an electric motor.

It is expected that the use of this machine will greatly reduce production costs. A vacuum packing process has been developed to handle the increased output. The expansion of the industry, of course, will depend primarily upon the supply of shrimp available on the trawling grounds.

## CRABS

Eight plants in southeast Alaska and five in the central district were engaged in the crab fishery in 1937, the operations in some instances being incidental to other fisheries. The Boardway Canning Co. at Wrangell was sold on February 1, 1937, to the A R B Packing Co. and was operated thereafter by the latter in connection with its salmon cannery. The Alaskan Glacier Sea Food Co. operated crab canneries at Hoonah and Cordova and also handled crabs at its shrimp establishments at Petersburg and Wrangell. The Gulf Packing Co. at Cordova and the Kayler-Otness, Inc., at Petersburg packed both salmon and crabs. A small crab cannery was established by the King Crab Co. in a leased building at Halibut Cove, on Cook Inlet, to pack both King and Dungeness crabs, but only a few dozen cases were prepared during the season. Other operators in the crab fishery were as follows: Ketchikan Sea Foods Co. Inc. (originally established as the Pacific Alaska Sea Foods Co., and later reorganized),

which took over the plant formerly owned by the White Packing Co., at Ketchikan; Oscar H. Wood, at Hoonah; Salt Sea Fisheries, at Tenakee; Scotty's Packing Co., Mummy Island; and S. E. Smith Packing Co., at Hartney Point.

The plant of Kayler-Otness, Inc., was destroyed by fire on November 22, 1937, with a property loss of \$6,000. Fire also destroyed the Salt Sea Fisheries plant in November 1937, resulting in an estimated

property loss of \$6,500.

The output of canned crabs increased about 84 percent over that of the previous year, the chief expansion being in the Cordova district. Cold-packed crab meat, on the other hand, showed a decline to the smallest production since 1923. Of the total crab products in Alaska in 1937, 69 percent were from the vicinity of Cordova and nearly 31

percent from southeast Alaska.

There were 467 persons engaged in the industry, of whom 315 were whites, 115 natives, and 37 Filipinos. Products consisted of 625,429 pounds of canned crab meat (1,105 cases of 6½-ounce cans, 16,079 cases of ½-pound cans, 726 cases of 13-ounce cans, and 1,569 cases of 1-pound cans, 48 to the case; 865 cases of 1-pound cans, 90 to the case; and 1,217 cases of 20-ounce cans, 24 to the case), valued at \$251,248; 62,047 pounds of cold-packed meat, valued at \$22,826; 467 pounds of crab meat in bulk, sold locally, valued at \$233; and 871 dozen whole crabs in the shell, valued at \$1,792. Except for 3,120 pounds of king crab (130 cases of ½-pound cans) valued at \$910, the entire production was of Dungeness crab. The total output of crab products in 1937 was 711,318 pounds, valued at \$276,099, as compared with 473,245 pounds, valued at \$158,874, in 1936, an increase of 50 percent in quantity and 74 percent in value.

## TROUT

Only a small commercial production of Dolly Varden and steelhead trout in Alaska was reported, all of which was incidental to other branches of the fisheries in the southeastern district. The reported products were as follows: Dolly Vardens, 41,740 pounds fresh, valued at \$2,966, and 2,545 pounds frozen, valued at \$255; steelheads, 17,714 pounds frozen, valued at \$1,627. The total output of both species was 61,999 pounds valued at \$4,848, as compared with 46,363 pounds valued at \$3,836 in 1936.

## MISCELLANEOUS FISHERY PRODUCTS

Fish of minor commercial importance are taken in limited quantities, chiefly in connection with the halibut fishery, and are landed in ports of Alaska and British Columbia and at Seattle. Such products landed in Alaska in 1937 were as follows: Sablefish, 4,063 pounds fresh, valued at \$110, 1,839,137 pounds frozen, valued at \$56,576, 190,185 pounds pickled, valued at \$6,794, and 69,582 pounds of livers, valued at \$27,833; rockfish, 16,843 pounds frozen, valued at \$336; flounders, 180,000 pounds fresh, valued at \$4,500; "lingcod," 743 pounds frozen, valued at \$15, and 2,264 pounds of livers, valued at \$906; and smelt, 275 pounds frozen, valued at \$8.

## FUR-SEAL INDUSTRY

## PRIBILOF ISLANDS

#### GENERAL ADMINISTRATIVE WORK

In 1937, 55,180 fur-seal skins were taken at the Pribilof Islands, an increase of 2,734 over the number taken in the preceding year. Of the skins secured on St. Paul Island, 41,383 were removed from the animals by the stripping process and blubbered before curing. The remaining 2,685 skins from that island and the entire take of 11,112 skins from St. George Island were removed by the skinning process.

Delivery was made to a representative of the Canadian Government at Seattle of 8,277 sealskins, representing 15 percent of the season's take, selected proportionately from the different sizes and grades, in accordance with provisions of the treaty of July 7, 1911. The remaining 46,903 skins were forwarded to the Fouke Fur Co. at St. Louis, Mo., for processing and sale at public auction. After the latter skins are sold, payment from the net proceeds will be made to Japan of its share of 15 percent of the season's take, due under the fur-seal treaty.

The byproducts plant at St. Paul Island was again operated for the utilization of fur-seal carcasses. Products for the season amounted to 29,830 gallons of oil and 165 tons of meal. These products, except for small quantities used at the Pribilof Islands for fox feed, were shipped to Seattle, where the oil was sold by competitive bidding and the meal was transferred to the Division of Fish Culture for feeding

fish in hatcheries throughout the country.

In the 1937–38 season there were taken on the Pribilof Islands, 863 foxskins, consisting of 231 blue and 15 white skins from St. Paul Island and 616 blue skins and 1 white skin from St. George Island.

Sealing and foxing activities were performed, as usual, by Pribilof natives under the direction of the Bureau's staff. Approximately 80 additional laborers from the Aleutian Islands were employed to assist

with sealing operations during the summer.

No important construction program was undertaken at the Pribilof Islands during the year, but work on the extension of roads was continued on both islands and some improvements were made in buildings and equipment. A substation on one of the western Aleutian Islands was established for the expansion of sea-otter investigations and patrol.

The operation of the radio station on St. Paul Island, previously maintained by the Navy Department, was taken over by the Bureau

on August 10.

A patrol for the protection of the fur-seal herd during its northward migration and while it remained in Bering Sea waters was maintained by Coast Guard cutters, which also rendered other assistance in the Bureau's work. The Navy Department detailed the U. S. S. Sirius to carry the annual shipment of supplies from Seattle to the Pribilof Islands and to bring out the season's take of sealskins.

## TRANSPORTATION OF SUPPLIES

The U. S. S. Sirius, supply vessel of the Navy, sailed from Seattle on July 28 with the annual shipment of supplies for the Pribilof Islands, which aggregated 888 tons of general freight and 100,901 board feet of lumber for St. Paul Island and 605 tons of freight and 27,546 board feet of lumber for St. George Island, a total of 1,493 tons and 128,447 board feet of lumber. Supplies were carried also for the Navy Department, the Coast and Geodetic Survey, and the Bureau of Indian Affairs at Dutch Harbor. The vessel arrived at the Pribilof Islands on August 6.

On the return trip to Seattle, which covered the period from August 14 to August 27, the vessel brought out 54,679 sealskins, approximately 162 tons of seal meal, and miscellaneous freight. Certain equipment and supplies of the Navy Department that were not transferred to the Bureau when it took over custody of the naval radio station on St. Paul Island were transported to Dutch Harbor by the

Sirius en route south.

Additional supplies for the Pribilof Islands were shipped during the year on the *Penguin*.

## POWER VESSEL "PENGUIN"

Five round trips between Seattle and the Pribilof Islands were made by the *Penguin* in 1937, carrying passengers and supplies. In addition, the vessel performed interisland service and made trips to Indian settlements along the Alaska Peninsula and the Aleutian Islands to transport native laborers hired for fur-seal work at the Pribilofs during the summer. Two trips were made to the western Aleutians—one in July and one in September—in connection with the sea-otter patrol.

A full cargo of freight, chiefly perishable foodstuffs, was carried on each trip from Seattle, and outgoing shipments from the islands included the 1936-37 take of foxskins, transported to Seattle in March,

and the fur-seal oil produced at the byproducts plant on St. Paul

Island, which was brought out in September and November.

The north-bound voyages of the *Penguin* were as follows: February 3–24; May 1–13; June 12–22; August 21–September 3; and October 14–26. South-bound voyages covered the following periods: February 27–March 20; May 19–30; August 2–12; September 19–October 1; and November 2–14. On these voyages transportation was furnished to 74 passengers for the Bureau, including 26 employees of the Fouke Fur Co. who assisted with the season's scaling activities at the islands, and 9 persons connected with the Bureau's salmon patrol and investigations in Alaska. The vessel also transported 25 passengers for the Navy, 6 for the Office of Indian Affairs, 3 for the Coast Guard, 1 for the Bureau of Lighthouses, 2 Territorial teachers, and 10 unofficial travelers.

Deputy Commissioner Charles E. Jackson and party transferred from the *Brant* to the *Penguin* at Unalaska on July 14 and were taken to the Pribilof Islands for observation of the fur-seal activities. From there the *Penguin* took them to Naknek, where they boarded the

Scoter on July 18.

The Penguin cruised 30,063 nautical miles during the year.

### ST. PAUL ISLAND RADIO STATION

Having augmented its radio facilities at Dutch Harbor, the Navy Department in 1937 discontinued as a part of the Coast Signal Service the operation of its combined radio transmitting and receiving

station and radio direction finder station at St. Paul Island.

In view of the activities of the Bureau of Fisheries at the Pribilof Islands and the need for maintaining radio service in that isolated region, a radio transmitter and three receivers, together with such associated equipment as required for their operation, two small radio telephone sets for interisland communication, and all the buildings at the radio station were made available for the use of the Department of Commerce under a revocable permit. Custody of the station was transferred to the latter department on August 10, 1937. In lieu of the radio direction finder, which was discontinued, a radiobeacon was installed by the Bureau of Lighthouses.

Under the conditions of transfer, (a) Navy personnel visiting the islands will inspect the Navy-owned equipment to insure it is in satisfactory operating condition and will make such repairs as may be necessary without labor charge; (b) spare parts, crystals, etc., for use with Navy-owned radio equipment may be purchased by the Department of Commerce through the navy yard at Puget Sound; (c) Navy-owned equipment which may become obsolete or which may not be required for further use will be reported to the Commandant, Navy Yard, Puget Sound, for removal; (d) additions, alterations, or replacements to existing buildings or equipment may be made by the Department of Commerce but will revert to the Navy in the event the radio station is retransferred to the Navy in the future; but items of miscellaneous material and equipment, such as furniture, furnishings, tools, etc., may be expended from the inventory without replacement at the discretion of the Secretary of Commerce; and (e) annotations of the itemized inventory of the Navyowned property will be made periodically by a representative of the

Department of Commerce and any major changes will be recorded and reported to the representative of the Commandant, Navy Yard,

Puget Sound, during his annual visit to the island.

Daily weather observations are transmitted direct to the Weather Bureau, which has maintained a meteorological station on St. Paul Island for a number of years in cooperation with the Navy Department. Such observations are of much value in connection with the forecast and warning service in Alaska and in the States.

Pending the appointment of a radio electrician who will serve as head operating engineer in charge of the power plant and other electric equipment on St. Paul Island, the work at this station has been carried on by Carl M. Hoverson in addition to his duties as

school teacher.

## ROADS

St. Paul Island.—The new scoria road toward Marunich on St. Paul Island, which branches westward from the Northeast Point Road near Halfway Point, was extended one-half mile. Considerable work was done in repairing Northeast Point Road, including the sodding of sand dunes along the roadway. Some repairs, also, were made on Zapadni Road. In the spring there was built a retaining wall for the road bank around Big Lake, where high water and continuous south winds had caused considerable damage during the winter.

St. George Island.—The Zapadni Road on St. George Island was extended 5,700 feet, of which 1,500 feet was a plank road and 4,200 feet was surfaced with scoria. Repair work carried on during the year included the leveling and resurfacing with scoria of sections of Staraya Artil Road, the old road by North Rookery, and West Road.

## BUILDINGS

St. Paul Island.—Excavations were made for the foundations of a new machine shop, and a new salt-water intake system for washing sealskins on St. Paul Island was completed. Extensive repairs were made on washhouse A, which was damaged by storm on the night of

November 8, 1937.

St. George Island.—Additional work was done in 1937 on buildings erected in the previous year on St. George Island—namely, the electric power and cold-storage plant and an extension of the garage, and the installation of cold-storage and power machinery and equipment was completed. No major construction projects were undertaken during the year.

## BYPRODUCTS PLANT

At the byproducts plant on St. Paul Island in 1937, 6,490 cubic feet of blubber, or about 337,480 pounds, and 31,260 fur-seal carcasses were rendered into oil and meal. Operations began on June 20 and were discontinued on August 4. The total products amounted to 377 barrels, or 20,234 gallons, of No. 1 oil; 172 barrels, or 9,596 gallons, of No. 2 oil; and 330,265 pounds of meal. The foregoing quantities in gallons represent averages of 53.67 gallons per barrel of No. 1 oil and 55.8 gallons per barrel of No. 2 oil, as determined from the products sold by weight upon the basis of 7½ pounds to the gallon.

The supply vessel *Sirius* brought to Seattle in August 324,265 pounds of meal, which was turned over to the Division of Fish Culture to be used as fish food at Federal hatcheries throughout the country. Later that division found that a part of the shipment was surplus to its needs, and 35,000 pounds of meal was turned over to the Bureau of Animal Industry, of the Department of Agriculture, to be used in the feeding of hogs at the experiment station at Miles City, Mont.

Shipments of fur-seal oil were brought to Seattle on the *Penguin*—372 barrels of No. 1 oil on the September voyage and 169 barrels of No. 2 oil in November. A barrel of the No. 1 oil was delivered to the Bureau of Entomology and Plant Quarantine, of the Department of Agriculture, for testing to determine whether it would be suitable for use in spraying activities in the gypsy and browntail moth work carried on in the New England States, in which work large quantities of menhaden oil have been used for a number of years. There was furnished also to the Oil, Fat, and Wax Section of the Bureau of Chemistry and Soils, Department of Agriculture, a 1-quart sample of oil for experimental purposes.

In November, 19,912 gallons of No. 1 fur-seal oil and 9,429½ gallons of No. 2 oil were sold at Seattle by competitive bidding for \$5,396.80. The No. 1 oil brought 20 cents a gallon and the No. 2 oil 15 cents a gallon, or decreases of about 37 and 48 percent, respectively, from the prices obtained for similar grades of oil in 1936. The general decline in prices of oils is attributed to an overproduc-

tion of cottonseed oil during the season.

#### NATIVES

#### CENSUS

On December 31, 1937, the total native population of St. Paul Island was 263, including 10 persons who were temporarily absent from the island. There were 13 births and 3 deaths during the year

The census of St. George Island on December 31, 1937, showed ε population of 163 natives, including 5 persons temporarily absent from the island. There were 5 births and 1 death during the year.

The total native population of both islands at the end of 1937 was 426, or an increase of 14 over the census of the previous year.

120, of all filefease of 14 over the census of the previous

### MEDICAL SERVICE

Two physicians stationed at the Pribilof Islands throughout the year gave medical aid to the natives and to Government employees and their families. The general health of the natives and the sanitary

conditions on both islands were good.

During the year two Pribilof natives were taken to Seattle on the *Penguin* and placed in the hospital of the United States Bureau of Indian Affairs at Tacoma, Wash., for special surgical treatment which could not be performed at the islands with the facilities available there. In one of these cases, a boy of 6 from St. George Island was operated on for cleft palate and harelip. He arrived at Seattle on March 20 and returned to St. George Island on the May trip of the *Penguin*. At least one more operation will be necessary before the deformity is corrected. The other case was that of a boy of 9 from

St. Paul Island, who was brought to Seattle on the Penguin in Novem-

ber for treatment of a tubercular ankle.

Another St. Paul Island native, who lost his left leg in an accident several years ago, was fitted with an artificial leg at Seattle. He came out from the island on the *Penguin* in November 1936 and returned in February 1937.

### SCHOOLS

The Bureau maintains schools for the native children on St. Paul and St. George Islands, and all children between the ages of 6 and 16 are required to attend. Two teachers are employed on each island. Instruction is confined to the elementary branches, including some manual training and home economics.

The 1936-37 school year began on September 15, 1936, on St. Paul Island and on September 21, 1936, on St. George Island; it

closed on May 7, 1937, on both islands.

On St. Paul Island there were 9 girls and 26 boys enrolled in the junior school, and 18 girls and 14 boys in the senior school, a total enrollment of 67. On St. George Island 10 girls and 11 boys were in the junior school and 14 girls and 8 boys in the senior school, a total of 43 pupils.

## SAVINGS ACCOUNTS

Ten Pribilof Islands natives have savings accounts in the bank of the Washington Loan & Trust Co., Washington, D. C., on which they receive interest, compounded semiannually. Effective March 1, 1937, the interest rate was reduced from  $2\frac{1}{2}$  to 2 percent. The Commissioner of Fisheries is the trustee of their funds. A summary of the trust account for the year 1937 is as follows:

On hand Jan. 1, 1937 Interest earned from Jan. 1 to Dec. 31, 1937	\$4, 746. 93 90. 11
Total Withdrawn by natives	
On hand Dec. 31, 1937	4, 202. 04

The following is an itemized statement of the funds, setting forth the individual accounts:

Funds of the Pribilof Islands natives in the custody of the United States Commissioner of Fisheries, as trustee, Dec. 31, 1937

Kozloff, Marina	137. 10	Merculief, Elizabeth Merculief, Erena	\$73. 37 517. 12
Lekanof, Tatiana (Mercu-		Merculief, George	111. 84
lief)	536. 53	Pankoff, Agrippina	210. 31
Lestenkof, Michael	434. 14	-	
Merculief, Alexandra	94. 66	Total	4, 202, 04
Merculief Daniel	425 76		

#### PAYMENTS FOR TAKING FUR-SEAL SKINS

Natives on the Pribilof Islands are paid for their labor in taking sealskins at specified rates per skin, with some additional compensation for special services. As the work is collective in character, workers on each island are divided into classes according to their skill and ability and the total amount for the island is apportioned among them, each man in a given class receiving an equal share.

On St. Paul Island the payments to natives in 1937 were at the rate of 60 cents per skin for the 44,068 sealskins taken, or a total of \$26,440.80, and in addition \$180 was paid to two foremen and four mess attendants.

Natives on St. George Island were paid at the rate of 75 cents per skin, the total in 1937 amounting to \$8,334 for the 11,112 sealskins taken, with an additional payment of \$100 to two native foremen.

Details of these payments are shown in the following table:

Payments to Pribilof Islands natives for taking fur-seal skins, calendar year 1937

	S	t. Paul Isla	nd	St. George Island			
Classification	Number of men	Share of each	Total	Number of men	Share of each	Total

Total	77		26, 620. 80	50		8, 434. 0	

#### PAYMENTS FOR TAKING FOXSKINS

For taking foxskins on the Pribilof Islands in the 1936–37 season the natives were paid at the rate of \$5 per skin. The total payments amounted to \$530 for the 106 foxskins taken on St. Paul Island and \$4,530 for the 906 skins taken on St. George Island, a total of \$5,060.

#### FUR SEALS

#### KILLINGS

In 1937, 55,180 fur seals were killed, of which 44,068 were taken on St. Paul Island and 11,112 on St. George Island. Details in regard to the killings are shown in the following tabulations:

#### AGE CLASSES

The age class of a male seal of the Pribilof Islands herd is determined from the length of its body. The classification was derived from measurements of a large number of pups branded in 1912 and killed in subsequent years. The limits of the various age classes are shown in the table following:

Age classes of male seals, Pribilof Islands

Age	Length (inches)	Age	Length (inches)
Yearlings	Up to 36.75	4-year-olds	46 to 51.75
	37 to 40.75	5-year-olds	52 to 57.75
	41 to 45.75	6-year-olds	58 to 63.75

## Ages of seals killed on Pribilof Islands, calendar year 1937

[On basis of classification shown in preceding table]

Age	St. Paul Island	St. George Island	Total
Yearling males 2-year-old males 3-year-old males 4-year-old males 5-year-old males Cows 1  Total	1, 433 40, 944 1, 566 4 117 44, 068	429 9,856 772 2 53	1, 862 50, 800 2, 338 6 170 55, 180

<sup>1</sup> Cows unavoidably and accidentally killed or found dead.

Some of the seals recorded in the above tabulation as 2-year-olds and 4-year-olds probably were 3-year-olds, as not all male seals of a given age fall within the length limits assigned for the males of that age. As far as possible, the killings in 1937 were confined to 3-year-old males.

## COMPUTATION OF FUR-SEAL HERD

The computation of the fur-seal herd in 1937 was made by Supt. H. J. Christoffers. As of August 10 the total of all classes was 1,839,119—a numerical increase of 149,376 over the figures for the preceding year. The detailed report will be found on pages 142 to 150 of this document. Following is a comparative statement of the numerical strength of the various elements of the fur-seal herd in the years 1926 to 1937, inclusive.

General comparison of computations of the seal herd on the Pribilof Islands, 1926 to 1937

Classes	1926	1927	1928	1929	1930	1931

#### FOXES

A herd of blue foxes is maintained on each of the two principal islands of the Pribilof group, where the animals roam at large and obtain their food during most of the year from birds, birds' eggs, and miscellaneous sea life abundant on the beaches. In the winter, when the natural supply of food is scarce, the foxes are fed prepared rations, consisting chiefly of biscuits made of cereals, seal meal, and seal oil. In December and January the animals are trapped for their pelts and a suitable number are reserved for future breeding requirements.

#### TRAPPING SEASON OF 1937-38

In the 1937–38 season there were taken 863 fox pelts, of which 847 were blue and 16 white. Two hundred and thirty-one blue and 15 white pelts were taken on St. Paul Island and 616 blue pelts and 1 white pelt on St. George Island.

There were trapped, marked, and released for breeding stock 59 male and 56 female foxes on St. Paul Island and 44 males and 41 females on St. George Island. The breeding reserve includes also a considerable number of animals that were not captured during the season.

## CORRECTION IN REPORT OF TRAPPING SEASON 1936-37

The report of foxing operations at the Pribilof Islands in the 1936–37 season showed a total take of 999 blue and 13 white foxskins. When these skins were graded by the Department's selling agents at St. Louis, Mo., however, it was found that one of the skins from St. Paul Island which was listed originally as white was a freak skin, more blue than white, and it was included with the blue skins in the sale. The records have been corrected, therefore, to show the 1936–37 season's take as 1,000 blue and 12 white foxskins.

#### REINDEER

St. Paul Island.—There were 1,673 reindeer counted on St. Paul Island on September 30, 1937, of which 420 were the young of the season. Eighty animals (70 males and 10 females) had been killed for food during the year. Of these, 36 were used at the mess of the Bureau, 2 by the naval radio station, 27½ by St. Paul Island natives, 10 by temporary native workmen, ½ by the Penguin, and 4 were shipped to St. George Island. The herd was in good condition.

St. George Island.—A count of the reindeer on St. George Island on October 16 showed 32 animals in the herd, of which 8 were this year's fawns. Five males and three females had been killed for food during the year. In April 1937 there were 45 reindeer counted on this island, including 12 young deer. The fall census, therefore, indicates that four of the young had died or been killed by the older bucks.

Apparently conditions on St. George Island are not favorable for the maintenance of more than a limited number of reindeer. In the first few years after their introduction on the Pribilof Islands, the reindeer increased rapidly, and by the end of 1916 there were 111 on St. Paul Island and 85 on St. George Island from an original stock of 25 and 15, respectively, transferred there in 1911. The herd on St. George Island reached its maximum in 1922 with an estimated total of 200 animals. From 1917 to 1926, inclusive, 194 reindeer were killed for food on St. George Island and 172 on St. Paul Island. Since 1926, however, only 16 animals have been taken for food on St. George Island, as compared with 299 on St. Paul Island. At present the herd on St. George Island is the smallest for any year since 1912, and there appears to be a surplus of males, these animals numbering more than 2 to 1 of the females.

#### FUR-SEAL SKINS

## SHIPMENTS

Six hundred and ninety-seven barrels containing 54,679 fur-seal skins taken on the Pribilof Islands in 1937 were shipped on the U. S. S. Sirius and arrived at Seattle on August 27. Fifteen barrels of blubber, having a gross weight of 8,192 pounds, also were brought to Seattle on the Sirius, for use by the Fouke Fur Co. in the tanning of sealskins.

Delivery of 8,277 skins packed in 104 barrels was made to a representative of the Canadian Government at Seattle on August 30, in accordance with provisions of the fur-seal treaty. The remaining

46,402 skins were forwarded by freight to the Fouke Fur Co. at St.

Louis, Mo., and arrived there on September 8, 1937.

Sevens barrels containing 501 sealskins taken on the Pribilof Islands in 1937 and specially cured for experimental purposes were brought to Seattle on the *Penguin* in August and were turned over to a representative of the Fouke Fur Co. on August 13 for shipment to St. Louis.

#### SALES

Two public auction sales of fur-seal skins taken on the Pribilof Islands were held at St. Louis in 1937—on April 19 and September 27, respectively—at which a total of 42,005 skins were sold for a gross sum of \$1,083,590. During the year, also, 963 sealskins taken on the Pribilof Islands were disposed of at private sales, under special authorization of the Secretary of Commerce, for a total of \$27,449.61. In the following detailed statements the sales of other sealskins by the Department of Commerce for the account of the Government are included, in order that the records may be complete.

April 19, 1937.—On April 19, 1937, 22,278 Pribilof Islands fur-seal skins, dressed, dyed, and machined, were sold for \$662,950. These skins consisted of 8,090 dyed black and 14,188 dyed safari brown.

September 27, 1937.—At the sale on September 27, 19,727 Pribilof Islands fur-seal skins were sold for \$420,640. Of these, 19,580 dressed, dyed, and machined, brought \$420,566.50, and 147 miscellaneous partly processed skins brought \$73.50. In addition, 214 fur-seal skins taken by the Japanese Government on Robben Island in 1936 and allotted to the United States as its share of such skins under provisions of the fur-seal treaty, were sold for \$3,772.50. Of these, 199 dressed, dyed, and machined skins, dyed safari brown, brought \$3,720, and the remaining 15 skins, unhaired and dressed, brought \$52.50.

Special sales.—During the year 963 Pribilof Islands fur-seal skins were sold under special authorization by the Department for advertising and promotional purposes, the gross sales amounting to \$27,449.61. Of these skins, 553 dyed safari brown brought \$15,438.75; 394 dyed

black, \$11,844.14; and 16 raw skins, \$166.72.

Further details in regard to the sales of sealskins by the Department of Commerce for the account of the Government in 1937 are given in the following tables:

#### DISPOSITION OF FUR-SEAL SKINS TAKEN ON PRIBILOF ISLANDS

On January 1, 1937, there were on hand 64,563 fur-seal skins taken on the Pribilof Islands. Of these, 64,545 were at St. Louis, Mo., and 18 at Washington. In 1937, 55,180 fur-seal skins were taken on the Pribilof Islands, of which 8,277 were allotted to the Government of the Dominion of Canada as its share of the season's take and the remaining 46,903 were shipped to St. Louis. Of the skins on hand at the beginning of the year, 42,968 were disposed of, leaving 21,595 unsold, which, with the 46,903 from the 1937 take, make a total of 68,498 on hand on December 31, 1937. The following tables show further details in regard to fur-seal skins taken on the Pribilof Islands, as well as details in regard to other Government fur-seal skins under the control of the Department of Commerce:

#### SHIPMENT AND SALE OF FOXSKINS

The 97 blue and 9 white foxskins taken on St. Paul Island and the 902 blue and 4 white foxskins taken on St. George Island in the season of 1936–37 were shipped from the islands on the *Penguin*, sailing on February 27. The vessel reached Seattle on March 20, and the foxskins were forwarded by express to the Department's selling agents at St. Louis, Mo.

At the public auction sale in St. Louis on April 19, 1937, 510 blue foxskins of the 1935–36 season's take were sold for \$15,084.50, an average of \$29.58 per skin. The maximum price was \$89, obtained for

each of a lot of six No. 1 silvery pelts.

On September 27, 1937, there were sold at public auction, at St. Louis, 499 blue and 11 white foxskins taken on the Pribilof Islands in the 1936–37 season. The blue pelts brought \$13,511, an average of \$27.08 each; and the white pelts brought \$131, an average of \$11.91 each. The maximum price was \$84, obtained for each of two No. 2 extra light pelts.

#### SEA-OTTER SKINS

Twelve sea-otter skins that had been forfeited to the Government in 1936 were sold at public auction on April 19, 1937, by the Department's

selling agents at St. Louis, Mo.

Four sea-otter pup skins were sold for \$8, and three other small skins for \$60; the remaining five brought \$865, the price ranging from \$60 to \$410 per skin. The total sales of sea-otter skins amounted to \$933.

#### FUR-SEAL PATROL

# UNITED STATES COAST GUARD

As in previous years, vessels of the Coast Guard were assigned by the Secretary of the Treasury to patrol the waters of the North Pacific Ocean and Bering Sea for the protection of fur seals and sea otters which have their breeding grounds in Alaskan territory.

The cutter Onondaga patrolled between the Oregon-Washington boundary and the Strait of Juan de Fuca from March 20 to April 1 and was then relieved by the cutter Redwing, which continued the patrol in that vicinity and northward to Dixon Entrance, southeast Alaska, until April 20. The cutter Tallapoosa carried on the patrol from Dixon Entrance to Unalaska from April 20 to May 15, and the sea-otter patrol along the Aleutian Islands from May 28 to August 6.

Vessels of the Coast Guard which patrolled in the North Pacific and Bering Sea, with base at Unalaska, were the cutter Ingham, from April 20 to July 28; the patrol boats Cyane and Morris, from April 20 to July 7 and July 20, respectively; the patrol boat Daphne, from July 1 to September 30; the patrol boat Alert, from July 15 to September 8; and the cutter Duane from July 15 to November 6. The cutter Northland made its annual cruise to the Arctic Ocean during the period from May 21 to October 1 and patrolled in Bering Sea and adjacent waters.

#### BUREAU OF FISHERIES

One vessel of the Bureau of Fisheries, the Scoter, participated in the fur-seal patrol for a short time off the coast of Washington in the spring of 1937 during the northward migration of the fur-seal herd. The vessel was stationed at Neah Bay from March 26 to April 9.

A. M. Rafn, special agent of the Bureau, was again stationed at Lapush, Wash., to observe sealing activities and secure compliance with provisions of the fur-seal treaty and the law giving effect thereto in respect to the prohibition of the use of power-propelled boats and of firearms in the taking of fur seals by aborigines. Mr. Rafn was on seal-patrol duty in the vicinity of Lapush from March 29 to May 21.

#### SEALING PRIVILEGES ACCORDED ABORIGINES

Under the provisions of the international treaty of July 7, 1911, for the protection of the fur seals of the North Pacific, Indians and other aborigines dwelling on the coasts of North America are permitted to hunt fur seals by primitive methods—that is, in boats propelled by oars or sails, and without the use of firearms—except that no one may engage in such sealing who is in the employment of other persons or under contract to deliver the skins to any person.

In 1937 there were taken and duly authenticated by officials of the respective Governments 2,832 fur-seal skins, of which 161 were taken by Indians under the jurisdiction of the United States and 2,671 by Indians of Canada. The details are as follows:

Washington.—Forty-five sealskins taken by Indians of Washington were authenticated. Of these, 10 were from male seals and 35 from The skins were taken by Indians of Lapush and Neah Bay in the months from January to May, inclusive, and were authenticated by A. M. Rafn, special agent of the Bureau, and by N. O. Nicholson, superintendent of the Taholah Indian Agency, Hoquiam, Wash.

Alaska.—One hundred and sixteen sealskins taken by natives of Sitka from February to May, inclusive, were authenticated by Bureau employees. Of these skins, 19 were from male and 97 from female

British Columbia.—Indians along the British Columbia coast took 2,671 fur-seal skins in 1937, according to an official report.

#### JAPANESE SEALSKINS DELIVERED TO THE UNITED STATES

In accordance with provisions of the fur-seal treaty of 1911 there were allotted to the United States 210 Japanese fur-seal skins, or 10 percent of the number taken by Japan on Robben Island in 1937. These skins were received by the Department's selling agents at St. Louis, Mo., on March 28, 1938.

#### SUBSTATION FOR SEA-OTTER PATROL

In order to provide for the expansion of sea-otter investigations and patrol, a substation was established on Amchitka Island in the western Aleutian Chain during the 1937 season. Workmen from the Pribilof Islands, together with building materials, equipment, and supplies, were carried to the island on the *Penguin*, sailing from St. Paul Island on July 2. Eight natives at Atka were also employed to assist in unloading cargo and in the erection of buildings. On July 6 work was started on the construction of the Bureau's buildings—a bunkhouse 16 by 32 feet for white employees, another 14 by 24 feet for natives, and a storehouse 14 by 32 feet. The *Penguin* sailed again for the Pribilofs on July 10, leaving two white employees to act as observers and three St. Paul natives and three Atka natives to complete the work on the buildings. The vessel returned for these men in September.

O. J. Murie, of the Bureau of Biological Survey, head of a party of investigators who started making a survey of the game resources of the Aleutian Islands in 1936, was on Amchitka Island in the 1937 season and cooperated with the Bureau of Fisheries employees in their

observations of sea otters in that vicinity.

# FUR-SEAL HABITAT GROUP FOR FIELD MUSEUM

Under a special permit issued by the Secretary of Commerce, a taxidermist of the Field Museum of Natural History, Chicago, visited the Pribilof Islands in 1937 and collected material for use in a fur-seal harem exhibit at the museum. Fur-seal specimens obtained on St. Paul Island consisted of 3 large bulls, 5 other large males, 18 pups, and 15 cows. The skins were of little or no commercial value, having been taken from animals found dead on the rookeries and from cows that were killed accidentally in the drives. Birds for the habitat group were collected on both St. Paul Island and St. George Island and included 21 specimens of the least auklet, 7 of the crested auklet, 9 sandpipers, and at least 1 each of the Pribilof sandpiper, paroquet, tufted puffin, horned puffin, turnstone, snow bunting, squaw duck, goose, hawk, loon, grebe, shearwater, jeiger, eider, fulmar, and gull.

# COMPUTATION OF FUR SEALS, PRIBILOF ISLANDS, 1937

By HARRY J. CHRISTOFFERS

The Pribilof Islands fur-seal herd this season showed every outward indication of being in a satisfactory condition. There was a considerable expansion of harem areas, as well as an ample supply of breeding bulls of all classes and a comparatively large number of 3-year-old males in drives at the end of the season.

From a commercial standpoint the Pribilof seals arrived in a very satisfactory manner. They were fairly well scattered throughout the entire season instead of coming in very large numbers for a short period only. Small drives mean less road skins, less damage in health of rejected seals, and, because it is not necessary to kill so fast, better prepared skins. The fact that drives held up so well to the end of July indicated that there were still plenty of 3-year-olds for the breed-

The number of bulls and other large males, 4 years old and older, in drives during the first part of the season, and to a lesser extent throughout the entire season, is making it increasingly hard to drive and to kill. This is a condition which cannot be remedied and which will become proportionately worse as the herd increases in size. How it will then be possible to hold drives without the loss of a great many animals is difficult to understand. The 4-year-olds are driven again and again throughout the season, an exhaustive process which is

probably the cause of many later deaths at sea.

During the latter part of the killing season there is always the problem of cows in drives. As the herd increases, the problem will become more and more acute. This condition requires even more serious consideration than that of the bulls, for a cow driven in a large pod of seals on a warm day soon becomes exhausted. Heretofore there have not been many recorded deaths from this cause, although at times there have been a great many cows in drives. It is during the warm seasons that the most damage occurs, because the harems break up early and large numbers of cows get into the drives. The many cows in drives that do not die from exhaustion and are not killed by mistake are the ones which deserve the most serious consideration. There are no records to show how many of these animals are driven nor how many of them later die from the effects of the exhaustion which they endure at this critical period when they are heavy with milk. The loss at sea from this cause must be enormous, in view of the fact that it represents not only the mother and her pup but also the loss of future unborn pups. It may be one of many contributing causes which together have prevented expected increases of killable seals.

At present it appears that the only way to alleviate this condition is to change the killable class from 3-year-olds to 4-year-olds. There are various reasons why this change seems desirable from the standpoint of benefiting the herd. The 4-year-olds, in general, arrive much earlier than the 3-year-olds. Sealing could be started at the usual time, or possibly a little later, and might be discontinued between July 15 and July 20, or at least before July 25, and still permit the taking of a considerably larger proportion of 4-year-olds than is now secured of the 3-year-olds. If weather conditions caused the seals to arrive later than normal, the 4-year-olds would nevertheless all be on hand by July 20, or at least before July 25.

Early discontinuing of commercial killings would prevent the driving of great numbers of females and 2-year-olds. The driving of females, particularly, should be avoided insofar as possible. As the number of animals in the drives increase, proportionately more die, both during the drives and later on as a result of exhaustion there-

from.

The discontinuing of sealing earlier in the season normally would reduce the number of stagey skins secured.

The only apparent loss from killing 4-year-olds rather than 3-year-olds would be that due to mortality during an additional year at sea. On the other hand, the 4-year-olds have larger, heavier furred skins, and they were killed by the commercial companies in preference to 3-year-olds.

Apparently the only logical way to change over to the killing of 4-year-olds would be to discontinue sealing entirely for a season, or to kill about 25,000 3-year-olds during one year and the next year kill only the proper proportion of 4-year-olds and leave all 3-year-olds

for the following year.

It appears certain that it would not be desirable intentionally to kill from two age classes during the same year, although it would thus be possible to discontinue sealing very early by killing half 3-year-olds and half 4-year-olds. This would not work out satisfactorily, for there would be the danger that in order to secure the expected increase in killings each year too many animals would be killed. In a short time there might be a shortage of breeding animals. During the past several seasons when there has been no appreciable increase of killable animals, too many would undoubtedly have been killed if killings had been from both the 3-year-old and 4-year-old classes and if they had been continued until the expected increase were secured. If such a course had been followed, there would now be a grave shortage of bulls, but as killings were from one class only, the condition in this respect is now very satisfactory.

It appears, also, that about the only way to secure a large percentage increase of killable seals, such as occurred in 1929, is to leave a larger proportion of killable seals for breeding purposes. This was clearly demonstrated in the results obtained from leaving increased reserves in 1923 and 1924. From 1923 to 1929 larger proportions of 3-year-olds were reserved for breeding. Probably, also, there were particularly favorable conditions at sea during this period. The returns from leaving these extra breeders were very favorable. We have had no increase for the past several years, however, although we have killed to the end of July and have made no special reserves of breeders.

This season it was the intention to discontinue sealing around July 25, but inasmuch as killings increased at that time and as harems had not broken up to any great extent it seemed desirable to continue

killing a few days longer.

The records show that proportionately more 2-year-olds and 4-year-olds were killed in 1937 than in any previous year. A great deal of this increase over the previous 2 years was due to changes which resulted in more accurate measuring of animals killed. The native clubbers formerly selected seals for killing according to their appearance; they recognized the 3-year-olds from certain characteristics. Now they try to kill according to size, regardless of age; that is, under the present system animals are not classed as 3-year-olds if they measure in a 2-year-old or 4-year-old class.

#### BULLS

A census was again taken of harem and idle bulls. Harems on portions of all rookeries were counted. Some areas on practically all large rookeries had to be estimated. The result should be a fairly accurate but conservative estimate of the number of breeding males on hand. Owing to the cool weather, harems were not badly broken

up at the time of the count. Most of the breeding bulls were still holding their positions and there were many more idle and surplus bulls on hand than during the preceding year, when the weather was

abnormally hot.

Although there appeared to be plenty of mature idle and surplus bulls on rookeries and hauling grounds, fighting was not excessive, and there were comparatively few injured bulls. The number of idle bulls and surplus bulls on hand does not seem to have a great deal to do with the amount of fighting, most of which takes place between the early arriving harem bulls, before the cows reach the islands. The later arriving idle and surplus bulls apparently do not feel strong enough to oust the stronger harem bulls from their positions. Later on, when the harem bull has lost his strength, the younger and stronger bulls may drive him from his position. Throughout the season most of the fighting is very short-lived. The weaker bull usually gives way after a jab or two.

It has often been stated that an excessive number of idle and surplus bulls leads to so much fighting that many cows and pups are killed. Some pups and cows are killed by the harem bulls, especially on the

flat areas, but not to the extent that might be expected.

Bulls in drives, especially during the early part of the season, cause considerable trouble, as they cannot move as fast as the younger animals and still they do not want to be left behind. Some become exhausted and fall by the wayside. Their skins are valueless.

#### AVERAGE HAREM

The average harem is determined on the basis of an increase of 8 percent for the cows. The estimated average harem for the two islands this season was 43.43. This may be considered as quite

satisfactory.

Aside from actual counts or estimates of males and females, observations indicated that there were sufficient breeding males on the rookeries this season. Even during the last week of July there were idle bulls in the rear of the rookeries, and a fair number of large males or surplus bulls in good condition were in the drives at the end of the season.

It is very important that a proper or sufficiently low average harem be maintained. If the average harem is too large it is clearly indicative that too many males have been killed. It does not hurt the herd to have a low average harem; but a high average harem, or, in other words, a shortage of breeding males, is a sure indication that all cows are not being bred.

#### PUPS AND COWS

No pup count having been made since 1922, an average rate of increase of 8 percent has been used each year since that date to

determine the number of cows and pups in the herd.

The percentage of dead pups determined by actual count in 1922 was again applied to show the number dead on each rookery. comparative purposes the dead pups are included in the total number of pups. The figures given are probably considerably under the actual number of dead pups. It is only reasonable to believe that the ratio of dead pups to living pups will increase considerably as the rookeries increase in size. An unfavorable cold wet season also causes a larger

percentage of dead pups.

It would be very desirable to make another complete pup count to check up on figures which have been estimated for the past 15 years. It is very probable that as the herd increases in size the rate of growth will become smaller. Unless some sort of epidemic reduces the herd at various intervals, a point will finally be reached where the size of the herd will remain practically constant. This condition must be reached sometime; otherwise seals, the same as any wild animals, would increase to the point where their natural growth would be the cause of their extermination. Some wild animals increase to a certain point and then remain fairly constant in numbers; others increase to a certain point and then are nearly exterminated by disease, parasites, or food shortage.

Insofar as known, there have been no natural causes of a reduction in the rate of growth of the seal herd within the past few years. There is no known condition which causes a shortage of food and, owing to the immense expanse over which the seals feed, it is not believed that there could be a food shortage. There have been, of late, no ravages of uncinaria, which at one time was, and again may be, the cause of

losing thousands of pups.

There are always a few seals infested with the mange or some furor hair-eating parasite. This year there seemed to be more females than usual with hair and fur badly eaten. This condition has not, however, at any time in the known history of the islands become of any great importance.

#### MORTALITY OF SEALS AT SEA

In 1925, as a result of information secured from branding operations, it was found necessary to increase the mortality rates of seals for the first 3 years of their existence. These mortality rates were used until they were proved to be incorrect; in 1929 the great increase in the number of 3-year-olds available for killing made it necessary to reduce the mortality rates to those used prior to 1925.

The following statement appeared in the report of the computa-

tion of fur seals at the Pribilof Islands in 1932:

It is believed that the large increase in the number of 3-year-olds available for killing during recent years was primarily the result of leaving a larger breeding reserve, rather than to any marked decrease in the mortality rate.

In 1937, 50,800 3-year-old males were killed. This was less than in 1933, when 52,747 were taken. This clearly indicates that for the past 4 years there has been a decrease rather than an increase in the 3-year-old males returning to the islands during the sealing season. It would appear that some abnormal condition must have caused an increase in mortality during this period. If there has been no abnormal condition, the mortality rates should be greater than at present. It is very possible that as the herd increases in size the mortality of pups and young animals also increases. Unless there is a very much greater increase in killable males within the next year or two, mortality rates must be materially increased and necessary adjustments made in all calculations.

At this time all evidence seems to point to the conclusion that the decrease in number of available 3-year-olds is due to closer killing since 1930. In 1929 killings were discontinued on July 24. From 1923 to 1929 proportionately larger breeding reserves were left than during any year since that period. The abnormally large increase of killings in 1929 was, according to the general belief, due to the leav-

ing of larger breeding reserves on and after 1923.

#### COMPLETE COMPUTATION

The following summary shows the methods used in computing the number of animals in the fur-seal herd of the Pribilof Islands in 1937. The total number of seals of all classes on August 10, 1937, was 1,839,-119, or 149,376 more than in 1936. This is an increase of 8.84 percent.

Complete computation of fur seals, Pribilof Islands, as of Aug. 10, 1937

Total theoretical bull stock for 1937 New increment of breeding bulls deducted			14, 733 5, 593
Surplus bulls, Aug. 10, 1937			9, 140

<sup>&</sup>lt;sup>1</sup> Estimates have been worked out, insofar as possible, to show the approximate number of seals of each class which should be credited to each island. The seals, however, do not haul out in accordance with figures given. Seals born on either island frequent the other island. They travel promiscuously between the two islands and haul out on either one. The total for both islands, however, is approximately correct.

APPENDIX III TO REPORT OF COMMISSIONER OF FISHERIES FOR THE FISCAL YEAR 1938

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1938

#### ADMINISTRATIVE REPORT SERIES

Since the beginning of the Administrative Report Series, considerable confusion has arisen concerning the system of numbering the separates composing it. much as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No. —." Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 24 were, they are numbered for filing purposes as follows:

- No. 1. Report, Commissioner of Fisheries, 1931.
- No. 2. Alaska Fishery and Fur-Seal Industries, 1930.
- No. 3. Fishery Industries of the United States, 1930.
- No. 4. Progress in Biological Inquiries, 1930.
- No. 5. Propagation and Distribution of Food Fishes, 1931.
- No. 6. Report, Commissioner of Fisheries, 1932. No. 7. Alaska Fishery and Fur-Seal Industries, 1931.
- No. 8. Fishery Industries of the United States, 1931.
- No. 9. Progress in Biological Inquiries, 1931.
- No. 10. Propagation and Distribution of Food Fishes, 1932.
  No. 11. Alaska Fishery and Fur-Seal Industries, 1932.
  No. 12. Progress in Biological Inquiries, 1932.
  No. 13. Fishery Industries of the United States, 1932.
  No. 14. Propagation and Distribution of Food Fishes, 1933.

- No. 15. Fishery Industries of the United States, 1933. No. 16. Alaska Fishery and Fur-Seal Industries, 1933.
- No. 17. Progress in Biological Inquiries, 1933.
- No. 18. Propagation and Distribution of Food Fishes, 1934.
- No. 19. Alaska Fishery and Fur-Seal Industries, 1934.
- No. 20. Fishery Industries of the United States, 1934.
- No. 21. Progress in Biological Inquiries, 1934.
- No. 22. Propagation and Distribution of Food Fishes, 1935.
- No. 23. Alaska Fishery and Fur-Seal Industries, 1935.
- No. 24. Fishery Industries of the United States, 1935.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the Report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

<sup>&</sup>lt;sup>1</sup> Administrative Report No. 32, Appendix III to the Report of the U.S. Commissioner of Fisheries, 1938, Approved for publication, June 23, 1938.

#### **FOREWORD**

This report constitutes a summary of the activities of the Division of Fishery Industries as well as a review of the fishery statistics collected by the Division during the past year. As its name indicates, this Division of the Bureau is concerned with the activities and welfare of the commercial fisheries and fishery industries and the fishermen and shoresmen engaged therein; the fish canning and preserving industries; and the trade in fishery products. Its functions include the conduct of studies or activities: (1) To determine the extent and magnitude of our aquatic resources and the commercial importance of our fishery industries; (2) to learn the economic condition of fishermen and shoresmen engaged in the fishery industry, their place in the national economy, and what measures can be taken to improve their well-being; (3) to determine the character, utility, and effectiveness of different forms of fishing apparatus and vessels, suggest improvements therein. and discourage the use of those forms which are unnecessarily destructive or unprofitable; (4) to learn the effect of fishing on the supply of fish and suggest measures to promote orderly and sustained production; (5) to study and develop fisheries for hitherto unutilized fishes; (6) to investigate the preservation of fishery products, suggest improved methods, and discourage wasteful practices in this field; (7) to ascertain what use can be made of aquatic products not now utilized to economic advantage; (8) to inquire into the nutritive value of aquatic foods for man and his domestic animals, and promote the consumption of these foods; (9) to ascertain the means and methods of transporting fishery products on land and sea and recommend economical practices; (10) to inquire into the condition and extent of the wholesale and retail trade in fishery products and promote the more orderly marketing of our fishery harvest; (11) to introduce useful foreign methods or processes of capture, preservation, utilization, or marketing fishery products; (12) to handle matters relative to the administration of the act which authorizes cooperative associations of producers of aquatic products; and (13) to conduct the fishery market news service authorized by act of Congress in 1937.

Results of the various technological, economic, and marketing investigations carried on by the Division are published in separate documents as each project is completed, and a brief résumé of each current project is contained in this report. Information obtained from statistical surveys is published in part 2 of this report, which includes all the detailed statistical information that has become available since issuance of the previous report, 2 together with such summarized statements and interpretations of the statistics as are deemed significant and

useful.

Part 1. OPERATIONS OF THE DIVISION

# COOPERATION WITH OTHER FEDERAL AGENCIES

In line with established policy, the Division cooperated during the year with other Federal agencies where their activities required information or advice concerning the technology, economics, or statistics of the fishery industries, and, similarly, this Division utilized the ex-

<sup>&</sup>lt;sup>2</sup> Fishery Industries of the United States, 1936, by R. H. Fiedler: Appendix I to the Report of the U. S. Commissioner of Fisheries for 1937, pp. 1-276.

perience of other Federal agencies where they could assist by furnish-

ing data or counsel in the work of this Division.

More specifically, both the economics and technological staffs cooperated with the Federal Surplus Commodities Corporation in connection with its purchase for relief agencies of surplus fish, and with the distribution of this fish to relief clients. The economics staff aided by determining the quantities and location of such stocks of fish to facilitate purchase, while the technological staff cooperated in assembling data on, and in conducting practical demonstrations of, the nutritive value of fishery products and fish cookery.

The technologists of the Division gave courses in canning fishery products to State Extension Service workers at the request of the State Extension Service of the United States Department of Agriculture.

Our technologists also rendered considerable assistance to chemists of the Bureau of Home Economics of the United States Department of Agriculture in assembling data on the chemical composition and food value of the leading commercial species of fish and shellfish. These data are to be incorporated by the Bureau of Home Economics in a revised publication on the composition of principal American food materials.

Chemists of the Food and Drug Administration, United States Department of Agriculture, conferred at length with our technologists for the purpose of obtaining information on methods of determining fatty acid in fish meal and the effect of the presence of relatively large amounts of fatty acid in fish meal on its feeding value.

Assistance was given by the statistical and economics staffs to members of the Rural Electrification Administration in connection with the importance of the commercial fisheries in certain areas of Virginia and

North Carolina in which that agency was conducting studies.

Our economists and statisticians were of considerable assistance to members of the staff of the Bureau of Chemistry and Soils in their assembly of historical data, especially of a statistical nature, relating to the domestic manufacture of fish scrap and meal.

In the conduct of several phases of economic and technological work, the Division received the cooperation of the International Fisheries Commission at Seattle, Wash. This included certain technical studies on halibut and halibut-liver oil, and the collection of economic and statistical data on the North Pacific halibut fishery.

The Bureau also has worked with various Federal agencies in obtaining statistical data on our fisheries. In a cooperative arrangement, the Bureau of Agricultural Economics, Department of Agriculture, furnished statistics on the volume of cold-storage holdings of fish and quantities frozen, and the health authorities in Washington, D. C., assisted in obtaining data on the volume of fish handled at the Municipal Fish Wharf and Market in this city. Cooperation was accorded the Bureau of the Census in obtaining for that Bureau figures on the volume of the quarterly production and holdings of fish oils in the United States.

In addition to the specifically enumerated instances of cooperation with other Federal agencies cited above, which are on a continuing basis or were of a more detailed nature, it should be stated that a very close relationship exists between this Division and many of those Federal agencies whose duties require an interest in fish in particular, foodstuffs or feedstuffs in general, or in the various marine activities.

The staff of the Division is in almost daily contact with some one or more of these Federal agencies in the exchange of information of inestimable value to the scientific work of the Federal establishment.

#### COOPERATION WITH STATE AGENCIES

The Bureau of Fisheries long ago began establishing cooperative relations with the States in fields of mutual interest and endeavor and, in succeeding years, has constantly encouraged, fostered, and expanded this cooperative plan of work. By working closely, whenever possible, with the members of the staffs of various State laboratories, institutions, and agencies, the Division has been able to increase the productivity of the relatively small staff and carry out cooperative investigations at considerably less cost.

During 1937, the following cooperative investigations with various

States were conducted:

At Washington State College, Pullman, Wash., the Seattle technological laboratory staff cooperated with Dr. J. S. Carver in carrying

on tests with poultry in the feeding of fish oils and meals.

As in past years members of the faculty and staff of the University of Washington, Seattle, Wash., worked in conjunction with the staff at the Seattle technological laboratory in the conduct of various studies or investigations relative to the preservation of fishery products of the Pacific coast. In addition, the University of Washington placed space at the disposal of members of the Seattle laboratory for the conduct of technological studies, for which space was not available in

the Bureau's building.

The University of Maryland and the Maryland State Agricultural Experiment Station, College Park, Md., have given excellent cooperation to our technological staff. Free space for the Bureau's laboratories in two of its buildings (discussed elsewhere in this report) has been provided by the University of Maryland, and both the University and the Maryland State Agricultural Experiment Station are conducting in their various laboratories and departments of animal husbandry cooperative studies of the feeding value of fishery byproducts. The members of the staffs of these two institutions who have worked closely with the College Park technological staff are Dr. L. B. Broughton, Head of the Chemistry Department; Dr. W. C. Supplee and Mr. L. E. Bopst, of the Chemistry Department; Dr. L. H. James, Head of the Department of Bacteriology; and Professor M. H. Berry of the Dairy Department. These cooperative investigations in the abovementioned State universities and institutions are described in greater detail elsewhere in this report.

The technologists of the Division of Fishery Industries cooperated with Mr. L. E. Bopst and other chemists of the Maryland State Chemistry Department in developing methods for determining fatty acid in fish meal and the effect of the presence of relatively large amounts of fatty acid in fish meal on the subsequent feeding value of

the fish meal.

Mr. Otto Lang, chemist of the Hooper Foundation, University of California, San Francisco, Calif., who is conducting and improving a State inspection service of fish as food, spent considerable time in conferences with our technologists in connection with the possible application of the Bureau's electrometric test for determining the relative

freshness of fish, and other methods developed by our technologists, to

his studies for the State of California.

Our technologists continued their active cooperation, during the past year, with the Minnesota and Virginia State Departments of Markets in connection with the extension and improvement of State marketing grades for fishery products sold in those States. In Virginia one of the Bureau's technologists assisted the State inspector in preparing grades for herring roe, discussed in detail elsewhere in this report.

In the conduct of its statistical research work, the Bureau obtains unusual cooperation from various States. The statistical surveys of the fisheries in the various States bordering on the Great Lakes, in the Pacific Coast States, and in Maryland, Virginia, and Delaware have been greatly facilitated by the cooperation obtained from the fishery agencies in these States. With this aid it is now only necessary for the Bureau to conduct partial surveys in these States to sup-

plement the data available from the fishery agencies.

In addition, in nearly every other State where commercial fishing is prosecuted, some type of cooperation in its statistical work is rendered the Bureau by the State fishery agencies or other organizations. This makes it possible for the Bureau to make statistical surveys of a greater portion of our fishery industries than otherwise would be possible.

# COOPERATION WITH FISHERY ADVISORY COMMITTEE

Members of the staff of the Division worked very closely during the year with the Fishery Advisory Committee of the Business Advisory Council for the Department of Commerce. This work took its principal form in the planning of demonstrations and preparation of informative material for the meeting of the Committee in Washington, D. C., on January 21 and 22, 1938.

As a part of the program arranged for the members of the Committee, the Division gave numerous demonstrations of its work. These included an historical review and discussion of current trends of our commercial fisheries, by the Chief of the Division, with the use of a specially prepared series of charts. The modern methods employed by the Bureau in preparing the large volume of fishery statistics which are collected and disseminated by the Bureau were demonstrated and explained by E. A. Power. Demonstrations of technological studies included an experimental method for the canning of the blue crab by N. D. Jarvis; the electrometric method for determining the freshness of fish, by J. M. Lemon and M. E. Stansby; a new method of treating fish by "controlled smoke" to obtain a uniform product, by W. T. Conn; experiments looking toward reduction of bacteria in fish by use of ultraviolet rays, by J. F. Puncochar; and methods for protein analysis of fish, by S. R. Pottinger. Recent studies relating to the food value of fish, and especially pointing out the large reserves of vitamins, proteins, and essential minerals contained in seafood, were discussed by J. R. Manning and others of the technological staff. These discussions were concerned with nutritional studies on fish oils, by C. F. Lee; fish proteins, by W. B. Lanham; and minerals in fishery products, by Hugo Nilson.

The Division also aided extensively in the planning of the seafood dinner held at the Mayflower Hotel on January 21, 1938, by members of the Fishery Advisory Committee and others. It further contributed numerous articles and graphic charts for the pamphlet entitled "Facts—The Key to Progress."

#### EXHIBITS AT EXPOSITIONS

During 1937, the Division continued its supervision of the Bureau's exhibits at the Texas Centennial Central Exposition at Dallas, Tex., and the Great Lakes Exposition at Cleveland, Ohio, both of which ran during second year; and arranged for displays for the Florida State Fair in Tampa, Fla., and the International Exposition of Paris, France. These exhibits attracted considerable attention from visitors and assisted materially in bringing before our people the need and value of fishery conservation.

#### TEXAS CENTENNIAL CENTRAL EXPOSITION

At the conclusion of this exposition, the main feature of the Bureau's display, consisting of a sport-fishing diorama, was sent to Tampa, Fla., and installed in the fisheries building of the Florida State Fair. This will remain on display there for the Pan American Exposition in Tampa in 1939.

#### GREAT LAKES EXPOSITION

At the conclusion of this exposition a portion of the display was loaned to the University Museums of the University of Michigan, Ann Arbor, Mich., for display in the fishery hall. This consisted of the mechanically-operated diorama depicting the effect of thermal conditions in Lake Erie on the commercial capture of fish, a diorama of fish-hatchery operations, models of Great Lakes fishery apparatus, a display explaining net preservative treatments, and miscellaneous canned fish products. Another portion of the display, consisting of a panel of articles made from fishery products, was loaned to the Conservation Division of the State of Ohio and placed on display in the Bureau's fish hatchery building at Put in Bay, Ohio.

#### INTERNATIONAL EXPOSITION AT PARIS. FRANCE

The Division prepared an exhibit of the Bureau's activities for use in the United States Government Building at this exposition in 1937. This consisted of a series of 24 colored transparencies of 16 by 20 inches each, arranged in a wall panel, and depicted the Alaska salmon fisheries, the Bureau's research work on fishery technology and biology, and its work in the propagation and distribution of fish. Each transparency was titled in both English and French. The Bureau was allotted \$250 for the preparation of this exhibit. At the conclusion of the Exposition the transparencies were returned to the Washington office.

#### NEW YORK WORLD'S FAIR, AND GOLDEN GATE EXPOSITION, 1939

Members of the Division have devoted considerable time to plans for Bureau exhibits at the New York World's Fair, 1939, and the Golden Gate Exposition, 1939, at San Francisco, Calif. Federal displays or exhibits for these two fairs will not be constructed by the various Government agencies, as heretofore. Rather, these agencies will advise the Federal Commissions for the fairs of their respective activities, and these then will be incorporated in theme dioramas, which are to be constructed by the Fair Commission for display in the respective Federal buildings at the two fairs. The work of the Bureau at the New York Fair will be depicted in the following themes: Conservation, food, industry, recreation, and territories; and in the conservation theme at the Golden Gate Exposition. A separate Government committee has been appointed to develop plans for each theme and members of the Division's staff are acting on the theme committees, as indicated above. For the science display at the Golden Gate Exposition the Bureau is lending its panels depicting the migration of the Alaska salmon, and the eels of the Atlantic Ocean.

Members of the Division are also working in close cooperation with the New York World's Fair Administration on the development of a special Fishery Building to house industry exhibits, both foreign and domestic, and displays of various State fishery agencies, conservation leagues, and others. This is the first time a fair administration has made plans for a separate building of this type. The fair administration is desirous of having a display in this building by the Bureau of Fisheries, but to this date it has been impossible to arrange for it since funds for the purpose have not been provided.

# SEVENTH WORLD'S POULTRY CONGRESS, 1939

Members of the Division also are cooperating with the United States Commission for the Seventh World's Poultry Congress in the preparation of an exhibit for display at Cleveland, Ohio, in July 1939, during the proceedings of the Congress. The Bureau's exhibit will consist of displays showing sources and manufacture of fish meal, oil, ground oyster shells, and other aquatic products which are used as feeds for poultry. The poultry industry is one of the principal consumers of these domestic fishery products, and it is expected the display will be of unusual benefit to industries manufacturing these commodities.

#### GENERAL

During the year the Division prepared exhibits for display at various sportsmen's fairs, and for several trade and professional association meetings which convened in Washington, D. C. These exhibits for use at the sportsmen's fairs consisted mainly of dioramas depicting the research work of the Bureau relative to fish propagation and oyster culture, while those for use at the trade meetings consisted of displays of the food value of fish, and charts and graphs showing the magnitude of the fisheries in the United States and Alaska.

During the past year the Bureau has experienced an unusual demand for display exhibits at various sportsmen's shows, fairs, and trade meetings and for window displays and school exhibits. These requests have come from groups in many parts of the country. Because of the costs involved the Bureau has been unable to fill these requests, except where it had material available from past fairs and where costs for transportation were not involved. This desire for exhibit material on the part of the general public indicates to the Bureau that many of our people are greatly interested in fishery conservation work, and that if it were possible to fill all the requests a greater portion of our population might obtain a clearer insight into the need for wildlife conser-

vation, and a better knowledge of what can be done to promote conservation.

#### ECONOMIC AND MARKETING INVESTIGATIONS

There is a constant demand upon the Division of Fishery Industries for studies of the economics of the commercial fisheries, including investigations having application to the various functions of the marketing of fishery commodities. It has been possible to undertake only a limited program of long-time or continuing studies of this kind with available personnel and funds during recent years. It was necessary to further curtail work of this type during the past year due to the large volume of time required of the regular staff in connection with the planning and organizing of the Market News Service, to be discussed later in this report. However, as is customary each year, many short-time economic studies were made in order to satisfy the urgent demands placed upon the Division. Such studies most frequently are conducted preliminary to or closely associated with administrative activities of the Bureau and usually are not published. Results of some of these studies which were made during the past year are discussed briefly in the following paragraphs.

#### SURPLUS-FISH SITUATION

A study of the surplus-fish situation was made by the staff of the Division during March, and the findings were presented on March 29, 1938, by the Chief of the Division at the hearings before the Committee on Merchant Marine and Fisheries of the House of Representatives on H. R. 9765 and S. 3595 relating to the purchase and distribution of products of the fishery industry. The study made

in the Division developed the following information:

Frozen and cured fish.—As of March 15, 1938, the holdings of frozen fishery products in cold-storage warehouses in the United States amounted to 45,700,000 pounds. This is 13,200,000 pounds in excess of the normal or 5-year average of the holdings as of March 15 and 5,900,000 pounds less than the holdings as of March 15, 1937. On March 15, 1937, the holdings were 22,371,000 pounds above normal, or 5-year average as of that date. Thus, the excess holdings this year on March 15 over the 5-year average are 9,100,000 pounds less than the holdings as of March 15, 1937, over the 5-year average, at that time. Under congressional authority in 1937, the Federal Surplus Commodities Corporation purchased a little over 12,000,000 pounds of fishery products (most of which was frozen) at a cost of about \$621,000.

The excess holdings as of March 15, 1938, over the 5-year average as of this date, were made up principally of dressed and filleted cod, haddock, and pollock, and shellfish (mostly shrimp), sablefish, rosefish, salmon (mostly fall and pink varieties) and halibut. On March 15, 1937, the excess over the 5-year average as of that date was accounted for mainly by the large holdings of whiting, various species

of groundfish (cod, haddock, pollock, etc.), and rosefish.

On March 15, 1938, the holdings of cured herring amounted to 13,200,000 pounds, or about 4,200,000 pounds less than on the same date a year ago, but about 2,500,000 pounds more than the 5-year average. On March 15, 1937, the holdings of cured herring were

about 6,400,000 pounds more than on the same date in 1936 and 7,500,-

000 pounds more than the 5-year average as of that date.

In 1937, the landings of fish at the principal New England ports (Boston and Gloucester, Mass., and Portland, Maine) where the bulk of the catch of fish by New England vessels is landed, amounted to 388,000,000 pounds or about 26,300,000 pounds less than the landings at these ports in 1936. Decreases were recorded mainly in the landings of mackerel, whiting, pollock, and rosefish. Several of these species are the same as those which had large cold-storage holdings on March 15, 1937. Several other species recorded minor decreases. Increases were recorded mainly by cod, hake, cusk, and flounders. Among these species which had excess holdings as of March 15, 1938, over the 5-year average as of this date, there were cod, hake. and cusk.

In 1937 there were 168,200,000 pounds of fishery products frozen in the United States compared with freezings of 179,300,000 pounds in 1936 and a 5-year average of 130,000,000 pounds. In 1937, it is estimated that 183,000,000 pounds of frozen fish were withdrawn from cold storage as compared with 159,000,000 pounds in 1936 and a 5-year average of 125,700,000 pounds.

Canned fish.—Figures on the estimated holdings of canned fish were obtained by telegram and letter from various fishery associations. It is assumed the following figures thus obtained refer to stocks held by

packers.

The holdings of canned tuna, in standard cases of 48 one-half pound cans to the case, as of March 15, 1938, were reported as 649,000 cases (15,600,000 pounds) compared with 247,000 cases (5,900,000 pounds) on the same date a year ago. No data are available as to the com-

parison of the holdings with a 5-year average.

The holdings of canned shrimp, in standard cases of 48 No. 1 cans to the case, as of March 15, 1938, amounted to 290,000 cases (4,400,000 pounds) compared with 60,000 cases (900,000 pounds) on the same date a year ago, and 118,000 cases (1,800,000 pounds) on March 15, 1936. There is no figure available as to the 5-year average as of March 15.

The holdings of canned oysters, in standard cases of 48 No. 1 cans to the case, were 122,000 cases (1,830,000 pounds) as of March 26, 1938, and 123,000 cases (1,850,000 pounds) as of April 1, 1937. No

data are available as to the 5-year average.

It is understood the carry-over of canned alewife roe in the Chesapeake Bay area is considerably greater as of March 15 this year than

the holdings as of March 15 a year ago.

There was no surplus stock of canned California sardines, in 1-pound oval cans, as of March 26, 1938, and the same condition obtained in March 1937. Most of the pack of California sardines is put up in

1-pound oval cans.

The holdings of canned Maine sardines in cases containing an average of about 35 pounds of fish to the case, were 350,000 cases (12,250,000 pounds) as of March 15, 1938, and about 215,000 cases (7,500,000 pounds) as of the same date a year ago. Information was not available as to the amount of the 5-year average as of March 15.

No data are available on the situation with respect to canned mackerel in California. It is doubtful, however, whether there is any

appreciable carry-over, since the pack in 1937 was considerably less than in 1936 or 1935.

Reports indicate that the holdings of canned salmon of all kinds, in standard cases of 48 1-pound cans to the case, as of February 28, 1938, amounted to 3,429,000 cases (165,000,000 pounds) compared with 1,337,000 cases (64,200,000 pounds) on February 28, 1937. According to an estimate obtained from the annual statistical number of the Pacific Fisherman, dated January 25, 1938, the 5-year average amounted to about 2,200,000 cases (105,600,000 pounds).

A summary of the above information indicates that the holdings of fishery products in the United States, on which data were obtained, approximated 260,000,000 pounds on March 15, 1938. This represents an excess of approximately 80 to 100 million pounds above

normal holdings.

An act, Public No. 542, to authorize the purchase and distribution of products of the fishing industry was approved on May 25, 1938. It provides:

That, out of any funds available to the Federal Surplus Commodities Corporation, not to exceed a sum equal to the difference between \$1,000,000 and the sum expended by such Corporation in carrying out the provisions of the joint resolution entitled "Joint resolution to make funds available to carry out the provisions of existing law authorizing the purchase and distribution of products of the fishing industry," approved April 12, 1937, may be used by such Corporation for the purpose of diverting surplus fish (including shellfish) and the products thereof from the normal channels of trade and commerce by acquiring them and providing for their distribution through Federal, State, and private relief channels.

#### IMPROVED COLD-STORAGE STATISTICS

Progressive fish dealers in our markets are cognizant of the approximate volume of current supplies of fresh fish in their marketing area. The amount of fish in cold storage is not so apparent to them, yet such supplies, which have an important influence on the markets for fresh fish, are frequently many times the volume of fresh fish on hand at any given time. In order that interested parties may be apprised of the amount of fish in cold storage and quantities frozen, the Division, with the cooperation of the Cold Storage Section of the Bureau of Agricultural Economics, publishes monthly and annually bulletins which include this information.

In order that these reports may be of the greatest value to interested parties, this Division and the Bureau of Agricultural Economics make frequent revisions in the questionnaires submitted to cold-storage firms in order that new commodities or those of growing importance may be incorporated in the report. Thus, separate classifications have been added in recent years for fillets of various species as their importance increased in our markets; a new classification was added for rosefish, which is the product of a virtually new fishery; and another was added for swordfish, due to the increasing volume of imports of this commodity in the frozen state from Japan and subsequent storage in domestic warehouses.

New species classifications will be added on July 15, 1938, for scallops, a large volume of which also is imported from Japan; for shrimp, the domestic freezing of which has increased rapidly in recent years; and for sea crawfish or spiny lobster tails which have been im-

ported in growing quantities, especially from South Africa.

Statistics of quantities of frozen fish moving in and out of cold storage and the amount of fish in cold storage are given daily and weekly, respectively, in the fishery news releases issued by the Division's market news offices in Boston, Mass., and New York, N. Y. This service is discussed in greater detail elsewhere in this section.

#### UNITED STATES FISHERIES OFF FOREIGN COUNTRIES

A study made during the year shows that about 14 percent of the value of the catch of the domestic fisheries is represented by products taken off foreign coasts. Specifically, the sources and classes of the more important of these products were as follows: Off Newfoundland and Nova Scotia, principally cod, haddock, and other groundfish, 151,000,000 pounds, valued at \$4,600,000; off the west coasts of Latin American countries, mainly tuna and tunalike fishes, 121,000,000 pounds, valued at \$5,900,000; off British Columbia, largely salmon and halibut, 16,000,000 pounds, valued at \$1,000,000; off the east coast of Mexico (Campeche Bank), chiefly red snappers and groupers, 4,000,000 pounds, valued at \$200,000; and off Australia, 1,508 whales (weight undetermined), from which were produced whale and sperm oil valued at \$1,300,000. It will be observed that the total value of the fisheries off foreign coasts to domestic fishermen was about \$13,000,000.

#### MIGRATORY FISH OF THE ATLANTIC AND GULF COASTS

Members of the Division's staff devoted a great deal of time during the year to the preparation of historical statistics and graphic charts of the catch of migratory fish and shellfish common to the Atlantic and Gulf coasts for use in the deliberations of the two eastern zones of the National Planning Council of Game and Commercial Fish Commissioners at their meeting with officials of this Bureau in

Atlantic City, N. J., on February 6, 1937.

The data prepared in this Division covered the trends of the catch of 17 important migratory fish and shellfish. These data were supplemented by members of the staff of the Division of Scientific Inquiry to include discussions of the physical characteristics and habits of these species, and all the material was included in Special Memorandum No. 3239, entitled "Migratory Fish of the Atlantic and Gulf Coasts." The species covered by the report were cod, haddock, flounders, mackerel, sea herring, whiting, scup, sea bass, shad, alewives, croakers, squeteagues, Spanish mackerel, mullet, lobsters, crabs, and shrimp.

#### COMMERCIAL FISHERIES OF THE WORLD

On the basis of the most recent available data, the United States, including Alaska, ranks first in value of annual yield of fishery products among the countries of the world and is exceeded only by Japan in the volume of the yield. The catch by commercial fishermen of the United States, based principally on data for 1936, amounted to 4,800,000,000 pounds, valued at \$93,000,000, while that of Japan, which is partly estimated, amounted to 6,600,000,000 pounds, valued at \$87,000,000. Other countries whose annual commercial fisheries catch exceeded 1 billion pounds were Union of Soviet Socialist

Republics, England (including Scotland, Northern Ireland and Wales), China, Norway, Canada and Germany. The world's annual commercial catch of fishery commodities is about 30,000,000,000 pounds, valued at \$730,000,000.

#### DOMESTIC MARKETS FOR LOBSTERS AND SPINY LOBSTERS

In view of the interest manifested in connection with the increasing imports of lobsters and spiny lobsters from foreign countries, the Division conducted a study of the trend in this trade.

Preliminary data, compiled by the Bureau of Foreign and Domestic Commerce, show that the imports of fresh and frozen products of both of these crustaceans during 1937 amounted to 14,700,000 pounds, and canned products 800,000 pounds, or a total of 15,500,000 pounds, exceeding the total imports in 1936 by 29 percent, and the average of the 10 years ending in 1936 by 43 percent. This increase is reflected entirely in the fresh and frozen products, there having been a downward trend in recent years in the imports of the canned

Large increases were recorded for imports of fresh and frozen lobsters and spiny lobsters during 1937. Specifically, the imports of fresh and frozen lobsters, which come almost entirely from Canada, increased from 8,800,000 pounds in 1936 to 10,700,000 pounds, or 21 This increase was most interesting in view of the percent, in 1937. fact that for several years prior to 1937 the total imports of this commodity had not reached 9,000,000 pounds. The imports of fresh and frozen spiny lobsters increased from 2,300,000 pounds in 1936 to 4,000,000 pounds in 1937, or 74 percent. Probably even of more interest in connection with the imports of fresh and frozen spiny lobsters is the fact that as late as 1932 imports amounted to only 763,000 pounds and during the decade prior to 1934 receipts from foreign countries had never exceeded 1,200,000 pounds.

The principal sources of our imports of spiny lobsters, in order of their importance, are Union of South Africa, British West Indies, Mexico and Cuba. Small quantities come from other tropical and

subtropical countries.

Among the important countries which supply us with fresh and frozen spiny lobsters, the Union of South Africa has made most rapid strides in marketing her product in this country. Imports from that country increased from 1,020 pounds in 1934 to 130,000 pounds in 1935, 570,000 pounds in 1936, and 1,700,000 pounds in 1937. Our imports from the British West Indies have grown nearly as rapidly, increasing from 290,000 pounds in 1934 to 1,100,000 pounds in 1937. Cuba's shipments to this country increased from 38,000 pounds in 1934 to 207,000 pounds in 1937. Imports from Mexico have varied between 840,000 pounds and 940,000 pounds during the past 4 years.

The domestic catch of lobsters in recent years has varied from about 10,000,000 pounds to 14,000,000 pounds and that of spiny lobsters

from 1,500,000 pounds to 1,900,000 pounds.

#### IMPORTATION OF COTTON FISH NETTING

The imports of cotton fish netting from foreign countries has been consistently increasing during the past 4 years, according to foreign trade statistics compiled by the Bureau of Foreign and Domestic

Commerce. In 1934, when the first import statistics of this commodity were published, our total receipts from foreign countries amounted to 338,000 pounds, valued at \$124,000. Preliminary data show that in 1937 imports amounted to 846,000 pounds, valued at \$255,000, representing increases of 150 percent in volume and 106 percent in

value in the 4-year period.

Of especial interest with relation to the domestic market for foreign produced netting is the fact that while in each of the years for which data are available Japan contributed most of our imports of this commodity, her percentage of the total volume of imports increased from 63 percent in 1934 to 95 percent in 1937. Other countries from which cotton fish netting was received in this country in 1937 were Netherlands and United Kingdom, with very small quantities from Canada, Germany, France, Belgium, and Czechoslovakia.

#### INTERCHANGEABILITY OF USES OF OILS AND FATS

In publications of the Bureau and in previous annual reports of this Division the technical and economic aspects of the general interchangeability of the uses of all saponifiable oils and fats of animal and vegetable origin, and their effect on markets for and uses of fish oils, have been discussed in considerable detail. Because of the influence of this factor on many important American industries, it has become of increasing interest and importance during the past year. Particularly has it been a factor to be considered in the Government's program of reciprocal trade agreements. Consequently, technologists and economists of this Division spent considerable time during 1937 in assembling special data on this subject from the Bureau's files for officials of the State Department, the Federal Trade Commission, the Bureau of Customs of the Treasury Department, members of Congress, and representatives of trade associations.

# ACTIVITIES OF THE FISHERY COMMITTEE OF THE NATIONAL ASSOCIATION OF MARKETING OFFICIALS

The Fishery Committee of the National Association of Marketing Officials was appointed in October 1936 at the association's convention in Nashville, Tenn., to deliberate on problems in connection with the marketing of fish which come before the association. While this is a very new committee, it already has shown much interest in fishery work and bears promise of most fruitful accomplishments in the future.

The members consist of J. H. Meek, Director, Division of Markets, Virginia, Chairman; Charles M. White, Chief, Division of Markets, Maine; and L. M. Rhodes, Commissioner of Markets, Florida. It will be observed that in each instance the members of the committee represent marketing agencies of States which are important in the

commercial production of fish and shellfish.

The first meeting of this committee, following its appointment, was held in Washington, D. C., on April 26, 1937. On that occasion, as a means of developing general policies and plans for study, it discussed nine questions having important bearing in connection with the marketing of fish. Answers which reflected the opinions of the committee were then reported at the Nineteenth Annual Convention of the National Association of Marketing Officials, held in New York

City on December 18, 1937. The questions and answers as developed

by the committee were as follows:

1. How can the State officials cooperate in the conduct of the Market News Service for fish, established July 1, 1937, by the United States Bureau of Fisheries?

It appears that the Market News service for fish in each State can be coordinated with the State Market News service for agricultural

commodities.

2. How can the State officials aid cooperative marketing associations of fish producers?

Give them the same support that is given producers of agricultural

 ${f commodities}$ 

3. Should the Federal Government extend loans to Fishery Cooperatives?

In the same way that loans are extended to cooperatives handling

agricultural commodities.

4. Should the State marketing or other State agencies take a greater interest in conducting economic studies of the marketing of fishery products?

Where there are economic studies relating to agricultural commodities, similar studies should be made relating to the marketing of

fishery products.

5. Should the State marketing or other State agencies aid in the conduct of a fishery extension service to aid producers in marketing improved fishery products and to acquaint housewives with the food value of fishery products?

The same as agricultural commodities or other foods.

6. Should schools and colleges give consideration to the teaching of fishery economic and technical subjects—especially in those States where fishing is an important industry?

This seems essential if proper progress is made.

7. Should a Federal-State inspection service, of voluntary nature, be established for fishery products?

It is exceedingly important that a voluntary Federal-State inspec-

tion service for fishery products be established without delay.

8. Should consideration be given to the establishment of small inexpensive warehouses at important fish-production centers to hold, temporarily, surplus supplies of fresh fish pending more favorable marketing conditions?

This is a matter that should be given careful consideration and

gradually developed to meet the needs of individual cases.

9. Should consideration be given the development of a fishery conservation plan along the line of the soil conservation subsidy?

This is needed to protect, conserve, and develop the industry. The Chief of the Division addressed the New York Convention of the National Association of Marketing Officials on December 18, using as his subject "Outline of Fishery Market News Service." This address was received with considerable interest, especially in connection with the application of this new work of the Division in the various States represented by the delegates.

At the time of the convention of the Atlantic States Division of the National Association of Marketing Officials, held in Washington, D. C., in April 1938, members of the association's Fishery Committee, marketing officials from other coastal States, the writer and members

of his staff, met to discuss policies of general cooperative activities in connection with the Division's new fishery market news service. It was pointed out by the Division's staff that funds were so limited for this new work that it would be impossible to communicate by telegraph on a daily basis the voluminous market information collected by the Division to State marketing offices for their dissemination to interested parties. Consequently, it was the concensus of the meeting that for the present these market news reports should be mailed to the State agencies and those having facilities would develop means for dissemination. It was further suggested that as the States developed suitable procedures for dissemination, adequate funds might be made available by the States to cover telegraph costs or to conduct some of the work of collection of data in their States, which would relieve the Division of portions of its expense in order that it could take over communication costs. The policy of mailing these market news reports to State marketing offices has been followed by the Division and some of the States have already indicated that they are conducting studies in connection with the marketing of fish in order that they may more intelligently disseminate this new type of information.

#### TRENDS OF THE BLUE CRAB INDUSTRY

An interesting geographical movement of the blue crab industry was revealed by a study of the official statistics of the products of this industry. As late as 1930 the States of Maryland and Virginia dominated the fishery for this crustacean, accounting for nearly 68,759,000 pounds. In that year the entire marine coastal area of the South Atlantic and Gulf States contributed only 7,024,000 pounds to the domestic catch. By 1936 the Chesapeake production had decreased to 43,670,000 pounds while that of the South Atlantic and Gulf States had increased to 29,831,000 pounds. The outstanding States contributing to this latter production in 1936 were Louisiana, 12,942,000 pounds; North Carolina, 6,591,000 pounds; and Florida, 3,194,000 pounds. With the development of this more southern crab fishery, fresh-cooked crab meat from the area is becoming a factor of increasing importance in the northern market.

For instance, the production of fresh-cooked crab meat in Louisiana in 1931 amounted to only 175,000 pounds, while in 1936 it had reached 1,035,000 pounds. During the same period the production of fresh-cooked crab meat in North Carolina increased from 188,000 pounds to 432,000 pounds, and in Florida from a practically nonexistent industry in 1931 to 316,000 pounds in 1936. This rapid growth of the fresh-cooked crab meat industry in the more southern States is contrasted with the decrease in the volume of fresh-cooked crab meat produced in the Chesapeake States from 5,794,000 pounds in 1931 to

3,581,000 pounds in 1936.

Of interest in connection with the domestic production of crab meat and its changing geographic trend are imports of foreign canned crab meat. According to preliminary data, imports of this commodity, which emanates principally from Japan, amounted to 11,157,000 pounds in 1937, which exceeds the imports in any year since 1931. The average imports for the 5 years prior to 1937 were 9,116,000 pounds.

#### THE ATLANTIC TUNA FISHERY

The fishery for tuna on the Atlantic coast in past years has been conducted almost entirely by sport fishermen; however, limited quantities have been taken incidentally in fisheries conducted primarily for The interest in the sport fishery for this species has other species. increased in recent years, and a considerable volume of the sportmen's catch frequently finds its way into our markets. In the capture of tuna, sport fishermen usually employ harpoons adapted from the swordfish fishery, hand lines, or troll lines. During the past year, several fares of tuna were reported landed at New England ports by vessels operating purse seines, which are one of the primary accepted gears used in the commercial fishery for tuna and tunalike fishes on the Pacific coast. Reports, of especial interest at this time, are that a modern purse seine vessel, the Western Explorer, has sailed from the Pacific coast through the Panama Canal to engage in a commercial fishery for tuna and mackerel in the New England fisheries and that the New England commercial fishery interests have already produced

limited packs of canned tuna.

The commercial exploitation of this species on the Atlantic coast will be observed with great interest, especially in view of the rapid growth and present importance of the tuna industry in California where the Pacific coast industry is centered. It is most interesting to observe that the catch of tuna and tunalike fishes in California was of little consequence prior to about 1910, but today the value of the catch of these species ranks second only to salmon among all of the fisheries of the Pacific Coast States. The catch of tuna and tunalike fishes in 1936 amounting to 132,470,000 pounds, valued at \$6,565,000 to the fishermen. Tuna also ranks among the most important fisheries of the world. Based upon the most recent available data, the world's annual catch amounted to 675,000,000 pounds, valued at about \$24,000,000. This represents about 2 percent of the volume and 3 percent of the value of the catch of the world's fisheries for all species. Japan alone contributed 68 percent to the world's catch of tuna. Following in order were the United States with 21 percent; Spain, 4 percent; France, 3 percent; and Portugal, 1 percent. Other countries whose annual catch exceeded 1,000,000 pounds were Italy, Algeria, Tunisia, and Tripolitania.

#### NORTH PACIFIC HALIBUT FISHERY

During the past year George Roger Chute, assistant fishery economist, continued his economic study of the halibut fishery and industry of the North Pacific which was discussed in last year's report. This investigation covers a study of halibut vessel operation, transportation, warehousing, merchandizing practices, consumer attitude toward halibut, and a chronology of the fishery from its inception on the North Pacific.

# GEOGRAPHICAL TRENDS IN THE PRODUCTION OF CANNED OYSTERS

The earliest oyster canning industry of any consequence in this country was centered on Chesapeake Bay. As late as 1921 Maryland was the principal producing State for canned and hermetically sealed oysters, contributing 153,000 standard cases to the United States total pack of 442,000 cases. More recently, the demand for shucked stock

and oysters in the shell has so completely utilized the available supply in the Chesapeake area that the canning of this mollusk in this region

has been almost abandoned.

As the pack decreased in the Chesapeake Bay, increasing quantities of oysters were canned on the Gulf coast to supply the important Middle Western market, and in 1936 the pack in Mississippi of 223,000 standard cases was more than half that of the entire Atlantic and Gulf coasts. However, a newer and most important source of canned oysters is the State of Washington, where the Japanese or Pacific oyster is canned. In 1931, the pack in Washington was less than 8,000 standard cases, but by 1936 the oyster canning industry in Washington had grown to the point where its pack amounted to 119,000 cases or 23 percent of the domestic production.

#### COMMERCIAL ASPECTS OF SEAWEED INDUSTRIES

Considerable interest is shown in the various seaweed industries of the United States as is evidenced by the numerous inquiries which the Bureau receives and by the relatively large number of business men interested in the possibilities of new ventures and developments in the utilization of seaweeds. During the past year, several large chemical manufacturers sent representatives to confer with the Division's technologists regarding the preparation and utilization of sodium alginate, a widely used product made from kelp. Much interest is also shown

in kelp meal as a mineral supplement for livestock rations.

With special reference to eel grass, it is of interest that this seaweed once furnished a considerable industry in New Jersey, Virginia, Maryland, and elsewhere along the Atlantic coast. An investigation made by the Division during the year brought out the fact that the current domestic requirements of this product are now furnished almost entirely from foreign sources. With the depletion of domestic beds of eel grass, the manufacturing consumers, who found it especially suitable as an insulating material, considered it necessary to import supplies from Nova Scotia, but more recently the supply has become limited there. It has, consequently, become necessary to import a European seaweed, although it is shorter and in other ways less suitable than the native product.

# MARKETS FOR PERIWINKLES (LITTORINA SP.)

A study was made during the year of the commercial aspects of the capture and marketing of periwinkles. Information obtained by the Division's agents indicates that periwinkles are rather abundant in New England and that a small quantity is shipped from Maine each year to wholesale markets in Boston and New York. They are packed for shipment in the shell with seaweed and ice in either boxes or barrels. Quantities of periwinkles also are taken in Rhode Island and are used there largely for bait, both in commercial and sport fishing, although some quantities are shipped from Rhode Island to the New York market. Shipments also arrive in Boston regularly by steamer from Nova Scotia. It is understood that the meat of this form is somewhat similar to that of the hard clam. A customary way of preparing it for food is by boiling in the shell, and the broth resulting therefrom constitutes the edible product which is most popular among people of Italian descent.

## STATISTICAL INVESTIGATIONS

Fishery statistics are collected by the Bureau to serve two principal purposes—biological and economic. For this reason the Bureau must plan its statistical surveys to obtain comprehensive data for furnishing a complete and reliable picture of the condition and trend of the fisheries. The collection and compilation of the great mass of data necessary involves many problems. The fisheries are broad in scope, including over 160 varieties of aquatic products which enter into commercial production. These, many of which are migratory, are taken by a great variety of types of gear in areas along our seacoast and in our interior lakes and streams. If the biological aspect is to be served, complete annual statistics are needed on each of these phases in every section. If the economic aspect is to be served, statistics are needed not only on the phases listed above relative to the biological aspect, but also on the price structure, the processing function, and on marketing and distributing.

Statistics on these latter phases of the industry should be collected and published as soon as possible after the close of the business transactions in order to be of maximum value to the industry and others interested in the fisheries. However, because of limited funds and personnel it has not been possible to collect and publish these figures as currently as desired. For the same reason it has not been possible to collect statistics on the fisheries of the entire United States on an

annual basis.

# BIOLOGICAL ASPECT

The biologial aspect must consider two problems—the conservation and sustained supply of the resource, and the prediction of future trends or yields. Since the fisheries are usually prosecuted in areas not under private ownership, the problem of the conservation of these fisheries is of national concern. It, therefore, is important that close watch be kept of the condition of the various fisheries to detect depletion so that remedial measures can be promulgated timely and wisely. For this reason it is imperative that current statistical data

be obtained on the yield of our fisheries.

These statistics then furnish the biologist with the background upon which to base his prediction of future trends and yields. This he does by coupling the statistical data with studies of the life history of the species. Difficulty is experienced in making these predictions because the supply (or population) of the species cannot be seen, as is the case with farm animals or crops. The more complete and more reliable the statistics on yield are, the better foundation the biologist has for conducting his studies. The Bureau, therefore, aims to obtain a complete picture of each individual fishery to further these biological studies.

# ECONOMIC ASPECT

When the fishery has been conserved, and trends and yields of the fishery have been predicted, the problem still remains of supplying the fishery trade with the information so essential to the conduct of its business activities. In these days of increased competition the very existence of the fishery industry must depend upon reliable economic and statistical information. Such material has been especially valuable during the past few years, when it has been used

in national planning. The Bureau, therefore, aims to make its statistical surveys so complete that the industry and the various governmental organizations may turn to it for reliable fishery statistics.

# SURVEYS CONDUCTED

The statistical surveys during 1937 were conducted under the immediate supervision of Edward A. Power, assistant statistician, and the general direction of Fred F. Johnson, Assistant Chief of the Division. These surveys included the collection and dissemination of statistics of the commercial catch and its value, operating units, and employment in the fisheries. In addition, data were collected on employment and compensation of those engaged in the fisheries as well as products of fishery wholesale and manufacturing establishments.

As previously mentioned, limited funds made it impossible to cover all the fishing areas of the country during the past year for 1936. However, the following areas were surveyed: Chesapeake States, South Atlantic and Gulf States, Pacific Coast States, and Lake States. Statistics of the fisheries of Alaska also were collected by the Alaska Division of the Bureau. Summaries of the production in those sections which were not surveyed during the year are included for the

most recent years available in part 2 of this report.

In addition to the above, statistics were collected on the following special phases: The landings of fish by American fishing vessels at the ports of Boston and Gloucester, Mass., Portland, Maine, and Seattle, Wash. (published monthly); catch of mackerel in the North Atlantic fishery; cold-storage holdings of frozen and cured fish and amount of fish frozen, which are furnished by the Bureau of Agricultural Economics (published monthly); production, consumption, and holdings of marine-animal oils of the United States and Alaska (published quarterly by the Bureau of the Census); production of canned fishery products and byproducts of the United States and Alaska; transactions on the sponge exchange at Tarpon Springs, Fla.; volume of fishery products handled at the Municipal Fish Wharf and Market, Washington, D. C.; and the volume of the United States foreign trade in fishery products, furnished by the Bureau of Foreign and Domestic Commerce.

The following statistical and marketing agents assisted in the collection and compilation of the statistical data: S. C. Denham, F. F. Dimick, W. H. Dumont, R. L. Greer, Wm. Hagen, Jr., V. E. Heffelfinger, H. J. Kumin, B. E. Lindgren, C. J. Robbins, V. J. Samson,

C. B. Tendick, and J. L. Whitcomb.

The reader is especially referred to the section in the latter part of this report entitled "Statistical Survey Procedure," which gives in detail the methods employed in the collection of fishery statistics and other pertinent information.

# FISHERY MARKET NEWS SERVICE

It is history that seasonal gluts and famines of fishery commodities in our markets have frequently resulted in disastrous financial losses to the fishery industries and much economic waste to the nation. Likewise, experience has shown that such conditions have been largely the result of inadequate market information available to producers, middlemen, and other interested parties. If there is to be economy

in marketing transactions, buyers must know where they can purchase supplies of fish most economically and producers must be able to sell to their best advantage. As a means of developing the more orderly and economic marketing of fishery commodities, the Seventy-fifth Congress provided funds for the establishment in the Bureau of Fisheries of a market news service for the commercial fisheries.

Essentially, this new service constitutes an exchange of market information between the fishermen or producers in fishing areas and the middlemen in terminal markets, with the Bureau of Fisheries acting as the service agency; that is, the agency for collecting and dis-

seminating the news.

This new work was inaugurated during the year under the immediate supervision of Andrew W. Anderson, marketing specialist, and the general direction of Fred F. Johnson, Assistant Chief of the Division. The early part of the fiscal year was devoted to exhaustive studies of methods used by other agencies in their administration of market news services and of conditions inherent in the fishery industry which might tend to influence the types of services having

greatest application and value.

New York City was chosen for the first fisheries market news office due to its importance as a terminal market and consuming center for fishery commodities from virtually every State wherein a commercial fishery is prosecuted. It also is an outstanding port of entry and terminal market for similar commodities from the maritime countries of the world. The annual consumption of fresh and frozen fish and shellfish in the New York metropolitan area is estimated at 400 million pounds, or about one-third of the total consumption of such commodities in the United States. Consequently, it was evident that current information on supply, demand, and prices in this market was of paramount value to the efficient conduct of the industry everywhere.

In November 1937 the market news staff proceeded to New York City and concentrated its attention on the development of the service The first daily report was published on February 14, 1938. This report, which is released in mimeographed form each day except Sunday and holidays, includes the following data covering the daily activities on the New York market: Volume of arrivals of fishery commodities by all types of carriers, separately enumerated by commodity classification and State, Province, or country of origin, with separate statements of the arrivals by express, rail freight, fishing craft, coastwise vessels, and transoceanic steamships; prices in both the salt-water and fresh-water markets; and movements of fish and shellfish into and out of cold storage. It further includes information on landings and prices at other ports where agents of the Bureau are stationed, such as Portland, Maine; Boston, Gloucester, Provincetown, and New Bedford, Mass.; and Seattle, Wash. Data received by telegram from the Seattle agent relating to landings of halibut at Prince Rupert, B. C., also are included. William H. Dumont, fisheries statistical and marketing agent, is in charge of the New York market news office.

Due to the outstanding importance of Boston as a producing port for fishery commodities, it was chosen for the second market news reporting office and the establishment of the service was started there early in 1938. The preliminary work in Boston was quickly com-

pleted and daily reports were issued beginning on May 26. The service at Boston is very similar to that in New York City. Detailed data are included in the daily reports on the landings of fish and shellfish at the Boston Fish Pier. These figures are separately enumerated by types of craft, fishing areas, and species. As in New York City, data also are included in these daily releases on prices, cold-storage movements, and arrivals at Boston by express, rail freight, fishing craft, and coastwise as well as transoceanic steamships. Data also are included on the landings and prices at other New England ports. at New York City, and at West coast ports. The Boston service further includes advance reports on certain fishery commodities en route to Boston, such as vessels with fares of mackerel passing through Cape Cod Canal, fish shipped by transporting vessels from Canadian ports, and express shipments clearing certain towns on the United-States-Canadian border in Maine. B. E. Lindgren, fisheries statistical and marketing agent, is in charge of the fishery market news service in Boston.

Studies are now in progress preliminary to the establishment of a market news reporting office in Seattle, Wash., and other offices will be established as time and facilities permit. Agents also will be stationed at other producing points to submit current market news

data to the reporting offices.

The popularity of the fisheries market news service with members of the fishery industry and others has been demonstrated by the many commendatory letters received by the Bureau about the work from fishery associations, wholesale fish dealers, cold-storage and freezing companies, transportation agencies, financing companies, Federal, State and Canadian fishery agencies, fishermen, and reporters and editors of newspapers and periodicals.

It will be the Division's aim to continue a sound market news service and to incorporate in this service as much useful current data from important producing and consuming centers as can be accurately collected with available facilities. Furthermore, every effort will be

exerted toward speed in dissemination.

# COOPERATIVE MARKETING

The work of the cooperative marketing unit of the Division, which is charged with handling matters relative to the administration of Public, No. 464, an act passed by the Seventy-third Congress, second session, authorizing associations of producers of aquatic products, was continued during the year under the direction of L. C. Salter, fishery

economist.

Since its establishment in 1935, the cooperative marketing unit has been conducting investigations to determine as far as possible the cooperative status of fishery organizations in the United States and the nature and extent of their activities and has given personal assistance to groups of fishermen contemplating the formation of cooperative associations. As part of this program, a survey of fishery associations on the Pacific coast was begun in 1936. During 1937 this was extended to include the fishing areas of the Atlantic and Gulf Coast States. Along with this survey, as a companion study, the unit has continued its investigation relating to the financing of fishing enterprises throughout the major fish-producing areas of the country.

It has been found that, among fishermen and associations visited, there is widespread interest in the possibilities of advancing cooperative marketing activities. This interest has been evidenced further by many requests for the Bureau to give aid of an advisory character concerning operations and management, and financing problems. Wherever possible, such assistance has been supplied through corre-

spondence, informative literature, or personal contact.

During the past year a form letter was sent to State marketing agencies of commercial fish-producing States, to learn the extent to which these agencies were engaged in fishery cooperative marketing work. Replies revealed that very little work of this nature was being done. It was indicated in some instances, however, that the organic law or subsequent acts of State legislatures provide that State marketing agencies might conduct work of this character, but that the lack of it in many cases had been due to failure of fishermen and their associations to request this type of assistance. Statements were made to the effect that if fishermen or their associations desired such assistance and suitable appropriations were made by the State, work in behalf of fishery cooperative marketing could be conducted readily.

At the request of the Director of the Extension Department of St. Francis Xavier University, Antigonish, Nova Scotia, the Bureau's cooperative marketing specialist attended the Fifteenth Annual Rural and Industrial Conference held at the university in August 1937 and delivered an address on fishery cooperative marketing in the United This conference was devoted to the discussion of social and economic phases of rural and industrial life of the Province of Nova Scotia, in which fishermen and fishery cooperative associations have played an important part. Following the conference, the Bureau's representative was given an excellent opportunity to study cooperative activity among the fisher-folk of Nova Scotia, and the adult education and extension work of the university in connection with its efforts to teach fishermen the principles of cooperative marketing and to help them organize and operate cooperative associations. At a specially arranged meeting, attended by the Bureau's representative, details of the history and development of the cooperative work in Nova Scotia were discussed, as well as present cooperative marketing activities and progress being made. At the close of the conference, arrangements were made for a group of the conference members to visit various fishing communities in Nova Scotia in which one or more cooperative projects were being conducted.

As a result of the address on fishery cooperative marketing in the United States delivered at St. Francis Xavier University, Rev. E. A. Kerr of St. Michael's Parish, Ridge, Md., who attended the Annual Rural and Industrial Conference, requested the Bureau's assistance in connection with proposed cooperative activities contemplated by a group of pound-net and oyster fishermen of his parish. In compliance with this request, three representatives of the Bureau attended a meeting of the fishermen at Ridge, on October 14, 1937, for the purpose of discussing with them plans which they had been considering for the organization of an association for the cooperative marketing of their fishery products. Our representatives outlined the work of the Bureau relating to fishery cooperative marketing activities; discussed the principles, functions, and operations of fishery cooperative associations; and offered advice and suggestions to enable this group of

fishermen to become thoroughly familiar with the functions of cooperation before attempting to solve their local problems by this method. Later, one of the Bureau's technologists assisted the group in solving

certain fishery processing problems.

Direct assistance also was given to a group of fishermen requesting assistance in the formation of a cooperative plan for the selling of shrimp at Thunderbolt, Ga. The Bureau's cooperative marketing specialist met with the group and later drew up a working agreement enabling these fishermen to operate cooperatively to sell their shrimp in an unincorporated manner until such time as sufficient funds would become available to properly organize and operate a cooperative marketing association.

At the meeting of members of the fishing industry at Atlantic City, N. J., in February 1937, members of the Bureau led a round-table discussion in which the work of the Bureau pertaining to fishery cooperative marketing was explained. Information also was supplied regarding what had been done among fishermen themselves in the United

States in the way of cooperative activity.

Aid and assistance also was given to the Southern New England Fishermen's Association, Mystic, Conn., in June 1937, as to methods

for improving markets for fishery produce.

In order to correlate the Bureau's cooperative marketing work with that of other agencies, our cooperative marketing specialist attended the meeting of the American Institute of Cooperation, at Ames, Iowa, in June, where he participated in round-table conferences concerning cooperative marketing and purchasing. Considerable interest was shown by this group in the work of the Bureau relative to the cooperative marketing of fishery products and mutual plans were developed for current exchange of information on cooperative enterprise.

While in Iowa, our cooperative marketing specialist conferred with representatives of the Iowa Conservation Department at their request, concerning the possibility of developing a plan for the cooperative marketing of carp and buffalofish taken in Iowa and adjoining States. These fishes are not highly prized in these States and, in an effort to rid their waters of them, the States have various contractual arrangements with the commercial fishermen. It was believed that if some type of cooperative marketing arrangement could be developed among those States that greater revenue could be derived from the sale of these fish.

In the spring of 1937 two bills (II. R. 6039 and II. R. 7309) were introduced into the United States House of Representatives, by Congressman S. O. Bland of Virginia, proposing the establishment of a fishery credit corporation for lending funds to fishermen's associations organized and operated in accordance with Public, No. 464, mentioned previously, and for the establishment of administrative agencies in connection therewith. Hearings on these bills were held on June 29 and July 16, 1937, before the Committee on Merchant Marine and Fisheries of the House of Representatives but at this writing the Congress has not yet acted on these bills.

The proceedings of these hearings have been published under the title "Fishery Credit Act, Hearings before the Committee on Merchant Marine and Fisheries, House of Representatives, Seventy-fifth Con-

gress, First Session, on H. R. 6039 and H. R. 7309."

On December 31, 1937, Mr. Salter resigned from the Bureau to accept employment as a cooperative specialist with the Tennessee Valley Authority, Knoxville, Tenn.

# TECHNOLOGICAL INVESTIGATIONS

Improvement of quality and increase in economic value of the products of our fishery industries constitute the goal toward which our technological investigations are directed and are constantly striving. The most modern tools of the various applied sciences are used in accomplishing these practical ends. This is conservation of a natural resource in its broadest and most effective meaning. For instance, it is comparable to the efforts of agricultural science in aiding farmers to make the most complete and valuable use of corn and cornstalks. In recent years much has been heard of a movement among scientists. known as the farm chemurgic. In a practical sense, this means teaching the farmer to direct the surplus products of his land, after food requirements have been met, to the factory as a source of supply of raw materials in the manufacture of industrial or nonfood products. In other words, the purpose of this movement is to bring agriculture and industry closer together and to make the farm a source for industrial raw materials. Likewise, fishery technology is serving not only to make more types of food available from the sea, but also is serving as the "sea chemurgic" to the "fishers of the sea," in teaching them to make valuable industrial commodities from fishery products, after primary food requirements have been met.

While our fishery technological studies have been of great value to the domestic fishery industries in increasing productive capacity and creating new wealth for the American people, their value to our domestic economy does not end there, for other American industries also are making great use of the results of our technological work. Many of these latter industries are consumers of raw materials produced by American fisheries and they follow our investigations very closely. At times, some have sent their technicians to our field and Washington laboratories where they have conferred with our technologists to keep abreast of the latest research developments. Following these contacts, some of these industries have applied the results of our researches

to the manufacture of their products.

For instance, in 1919, the Bureau of Fisheries pioneered in the development in this country of quick-freezing methods in the preservation of a food product and has continued researches in the frozen food field ever since. Other food industries have been quick to grasp the significance of this work and now the quick-freezing of fruits, vegetables,

and meats has become one of our major industries.

In another instance, the Bureau pioneered in searches for new sources of vitamins A and D and found that the oil from the livers of many species of fish are potent in these vitamins. Heretofore, only the livers of cod were thought to be useful for this purpose. The drug industry took advantage of this work and now produces many thousands of gallons of oil high in vitamins A and D from fish livers and fish viscera which formerly were discarded by the fishermen at sea. Likewise, our researches on the value of fish meal for feeding domestic animals have been of great value to the feed industry of this country.

A few years ago, the Division's technologists developed a smokehouse for curing fish which automatically controlled the temperature, humidity, and volume of smoke. In semicommercial operation, this produced a product which had a pleasing appearance and taste and one which was a considerable improvement over the usual smoked fish product prepared by "rule-of-thumb" methods. Many members of the fishery industry made use of this work and are now producing a better smoked fish product than heretofore. It has recently come to the attention of the Bureau that the results of this work are also being applied to the commercial smoking of meat products by the meat packing industry.

Our technologists are now conducting a cooperative investigation with a company interested in the temporary chemical preservation of fishery products until they can be concentrated at a central point for conversion into useful byproducts. The results of this work have been applied commercially to the preservation of various types of fish and fish products. In addition, the renderers of byproducts of the meat industry have taken advantage of this development to their economic

Several years ago, researches of the Bureau revealed that fishery products as a class are higher in iodine than most foods from land As is well known, iodine is a mineral essential in the diet of man and animals. The fishery industry made considerable use of this knowledge attained by the Bureau to promote the increased consumption of aquatic foods. In addition, the salt industry utilized the scientific facts and now markets a product known as iodized table salt which is the usual salt to which a small amount of iodine has been added.

## LABORATORIES

During 1937, the Division carried on its technological studies under the direction of Dr. J. R. Manning, senior technologist, at its laboratories located in Washington, D. C., College Park, Md., and Seattle, Wash. In addition, certain cooperative investigations were conducted by members of our technological staff in the laboratories of the University of Maryland, and Maryland State Agricultural Experiment Station at College Park, Md.; the University of Washington, Seattle, Wash.; and Washington State College, Pullman,

Construction of the small technological laboratory building in Seattle, Wash., referred to in last year's report, was completed. Heat, light, power, and plumbing facilities were installed and a greater portion of the Bureau's experimental equipment was set up in readi-Actual experimental work was undertaken shortly ness for operation.

after January 1, 1938.

The building was designed to provide facilities for setting up experimental machinery and equipment necessary in investigating methods for preserving and utilizing fishery products. It is of frame construction, 26 feet wide and 40 feet long. The walls of wood are 11 feet high and are planned for future brick veneer. The concrete floor slopes to a center drain. The standard equipment includes a 10-horsepower, high-pressure, oil-fired steam boiler, a steam-jacketed dryer, vacuum pump and condenser, an hydraulic press, a filter press, three centrifugal separators, a hammer mill, an attrition mill,

an iron mill, a Wiley mill, a bone cutter, a refrigeration machine and cold storage cabinet, and miscellaneous jacketed cooking kettles. These are further supplemented by recording instruments and miscellaneous experimental equipment developed in the course of investigative work. The laboratory has both hot and cold water, a large wash sink, complete lavatory fixtures, and will be heated by an extended surface steam heater. All motive power is by electric motor, either direct or by line shaft, and adequate light, power, water, and gas outlets are provided around the laboratory. This building is a valuable addition to the Bureau's facilities for carrying on technological investigations and will permit semicommercial work heretofore impossible at the Seattle laboratory.

During 1937 our technological investigations in general were delayed or suffered from lack of suitable and sufficient space. Particularly was this true at our technological laboratories at College

Park, Md.

# PRESERVATION OF FISHERY PRODUCTS FOR FOOD

Studies during 1937 in the preservation of fishery products for food were conducted in the Bureau's technological laboratories at College Park, Md., Washington, D. C., and Seattle, Wash. The investigations in the College Park Laboratory were carried on under the supervision of James M. Lemon, technologist in charge, assisted by W. T. Conn, assistant technologist; S. R. Pottinger, junior technologist; M. E. Stansby, junior chemist; Joseph F. Puncochar, junior bacteriologist; William B. Lanham, Jr., junior chemist; Willis H. Baldwin, Hillman C. Harris, L. F. Ortenzio and C. E. Swift, research associates and student assistants; in the Seattle laboratory under the supervision of Roger W. Harrison, technologist in charge, assisted by Robert E. Silver, junior chemist; Charles Butler, William Clegg, Louis Simenson, Marie Sater, and Rhea Waterberry, chemists, assigned to our laboratory by the Works Progress Administration; and Leslie Lowen, Neil Nellis, and Robert Rucker, research associates and student assistants; and in the Washington laboratory by Norman D. Jarvis, assistant technologist in charge of experimental canning investigations, and Agnes I. Webster, fish cookery expert.

# ELECTROMETRIC TESTS FOR DETERMINING THE FRESHNESS OF FISH

Several years ago an electrometric method or test for determining the relative freshness or degree of quality of fresh haddock was developed by M. E. Stansby and J. M. Lemon of our technological staff. During the ensuing years these men have been engaged in perfecting this method and in extending its application to the determination of the quality of fresh cod and pollock. In the meantime, as stated in the 1936 Division report, considerable interest was aroused by the industry in the possible commercial application of this test. In the original development of the method, the apparatus was designed for the testing of not more than four samples, simultaneously. This was one of the difficulties which was encountered when attempts were made by one of the large fishery producers in 1936 to use the test in commercial practice. At the request of this firm, and with its cooperation, the Bureau detailed M. E. Stansby to work with technologists of the

firm for the purpose of designing an apparatus which could be used commercially and which would enable an operator to make a greater number of tests simultaneously. Mr. Stansby was engaged in this cooperative detail from July 15, 1937, until the end of the year and, as a result of this work, designed equipment which can make determinations upon 10 samples of fish at one time. Thus, it is possible for the firm to make very rapid tests for the freshness of fish purchased, by means of this new apparatus, without delaying their packing activities. Ordinarily, 15 to 30 minutes were required for testing one sample. However, with the new apparatus, it is now possible for the operator to run the 10 samples in the same length of time and the test is now rapid enough to be used in the ordinary commercial control laboratory. The design of the apparatus is also quite simple and it is easy to manip-After a little practice an operator, without advanced scientific training, can obtain excellent results. At the present time this equipment is being used by the firm, in whose laboratories it was developed on a commercial basis, for the selection of fish which are to be used in packs of frozen products.

#### STUDIES OF RANCIDITY IN FISH

For the past several years we have studied the causes of rancidity in various fishery products and have worked on methods for its prevention which might have promise of commercial application. This work has been done in cooperation with the Musher Foundation, Inc., New York City, by research associates employed by the Foundation and stationed in our laboratories both at College Park, Md., and Seattle, Wash.

Several phases of this work which were conducted at our laboratories at College Park and which were described in last year's report, were completed and the results published in the following reports: "Oat Flour as an Anti-oxidant in the Salt Mackerel Industry," by J. M. Lemon, M. E. Stansby, and C. E. Swift, Food, vol. 6, No. 71, pages 441–443, August 1937, 33 Tothill St., Westminster, London, S. W. 1, and Food Industries, vol. 9, No. 10, October 1937, McGraw Hill Publish Co., New York, N. Y.

Other phases of this work were conducted in our Seattle laboratory where studies were made by the research associate of the Foundation of the effectiveness of cereal flours and cereal flour extracts in preventing the development of rancidity and the destruction of vitamin A in fish oils and fish liver oils, and the usefulness of these materials in preventing deterioration in other preserved fishery products. As a result of this work, it was found that cereal flours and their extracts have a mild antioxidant action on these products. In the case of fish oils and fish liver oils the effect was due to retarding the rate of oxidation rather than preventing it for any extended period. In the case of the vitamin active oils, vitamin A destruction corresponded with autocatalytic oxidation; therefore, the cereal flours did not materially increase the period before destruction began but decreased the rate of destruction. On the basis of organoleptic examination, treated oils appeared to be less rancid than untreated oils with a similar degree of oxidation as shown by the peroxide test.

When cereal flours were dusted on dressed salmon or sardines just prior to canning, or the extracts were sprayed on the fish or in the can. the canned products in general had a less pronounced odor and flavor during early storage but the advantage seemed to disappear soon.

The addition of cereal flours to brine used in the preparation of mild cured and kippered salmon did not show any detectable improvement in the quality of the product. On the other hand, canned Maine sardines prepared from fish treated with salt and oat flour in the hold of the boat during transit to the cannery showed some improvement over those to which salt alone had been added.

Spraying cereal extract on the surface of spiced herring resulted in the treated samples having a definitely better odor and flavor than

the untreated samples after extended storage.

Studies on these and other aspects of the possible utility of the cereal flours is being continued by the research associates of the Musher Foundation.

# STUDIES OF LACTIC ACID AS A POSSIBLE INDEX OF DECOMPOSITION IN FROZEN FISH

In order to simplify understanding of the problem, decomposition of fish might be classified into three general types. These are: (1) Enzymatic decomposition, or the action of enzymes, already present in the fish when alive, and which begin to break down the more complex compounds in the fish into simpler substances; (2) the deterioration or oxidation of the oil in the fish; and (3) bacterial decomposition.

When fish are frozen the bacterial action is arrested, since the bacteria are almost entirely killed at freezing temperatures. However, the other two types of decomposition in fish proceed but at a much slower rate than if the fish were not frozen nor held at low tempera-The problem of rancidity or oxidation in fish is discussed elsewhere in this report. Therefore, we are concerned here with enzymatic decomposition. It is known that one of the indications of the action of enzymes in fish, immediately after death, is an increase in the formation of lactic acid. Since lactic acid is a definite chemical compound and its quantities in fish can be accurately determined by analysis, our technologists decided that the amounts of lactic acid formed in fish at various stages of decomposition might be used as a reliable index of the progress, rate, or stage of decomposition or, to put it another way, it might be an accurate means of measuring the relative freshness of fish, somewhat similar to the use of the electrometric method for determining the relative freshness of fish, discussed elsewhere in this report.

Therefore, during the summer of 1937, Willis H. Baldwin, graduate student assistant, was temporarily assigned to duty at the Maryland State Marine Biological Station at Solomons Island, Md., for the purpose of procuring and freezing samples of fish to be used in a study of this project. It was necessary for the investigator to obtain these fish himself so that he would have a complete history and control of the fish from the time they were taken from the water until they had passed through the progressive stages of chemical changes accompanying decomposition to a point where they would be no longer fit for use as food. In some instances, fish were actually taken from the water alive and killed or were frozen, while alive, and the amounts of lactic acid determined in each sample immediately after freezing. These samples were then brought to our technological laboratory at College

Park where they were stored in a low temperature refrigerator and analyzed for lactic acid content at regular intervals during the entire

period of storage.

Since this work was not begun until late in 1937, we are not in a position to report any definite conclusions at this time. However, it was found that fish which were frozen alive, and others which were frozen in rigor, had a lower lactic acid content after storage of 4 months than fish packed fresh in ice for 3 days, but still in rigor and then frozen and held in storage for 4 months. Still higher percentages of lactic acid were shown in fish, not kept in ice, but frozen 3 days after death and on which determinations were made after 4 months of storage. It is possible that this study may not only yield another reliable index of decomposition but it may also reveal data which might enable our technologists to develop means of preventing or arresting enzymatic decomposition in fish.

### IDENTIFICATION OF CANNED SALMON

The utility of a test for identifying canned salmon according to species was discussed in last year's report, and certain data were given which suggested the possibility of identification on the basis of the refractive index and color of the free oil in the can. During the past year our technologists examined oil samples from approximately 1,000 cans of salmon which were selected as representative of the 1936 season's pack, and found that there was considerable overlapping of the refractive index and color of the oil between the species. This, therefore, precludes the use of this test as an infallible means of identifying canned salmon.

# CHANGES IN THE COMPOSITION OF PINK SALMON (One or hynchus gorbuscha)

In 1936 the Bureau published Investigational Report No. 33 entitled, "Physical and Chemical Changes in the Pink Salmon During the Spawning Migration," by Frederick A. Davidson, Division of Scientific Inquiry of the Bureau, and O. Eugene Shostrom, National Canners Association, Seattle, Wash. Since the pink salmon is one of our most important species of food fish, used almost entirely for canning, our Seattle technological laboratory at the beginning of the salmon season in 1937, and with the assistance of chemically trained personnel supplied by the Works Progress Administration, undertook a further study of individual fish of each sex as to gross composition, such as percentage of fat, ash, protein, moisture, water soluble nitrogen compounds, heat coagulable nitrogen compounds, free amino nitrogen, copper precipitable nitrogen, and phosphotungstic acid precipitable These analyses for gross composition indicate that while the fat content decreases and moisture content increases, during the course of the spawning season, there is very little if any apparent change in the composition or nature of the protein until the fish reach fresh water. In addition, purified protein material was prepared from the samples and reserved for subsequent quantitative measurement of certain essential amino acids.

#### CANNING AQUATIC PRODUCTS

During 1937 the series of experimental packs in the study of home canning methods was completed, and packs previously prepared were examined to gather data for a final report on improved methods for home or noncommercial canning. Data obtained during the year indicated that such fresh-water varieties as the carp, hitherto regarded as unsuitable for canning, could be prepared as a canned product of good quality, by home or noncommercial canners, thereby opening the door for wider utilization and conservation of fishery resources in the interior of the country, as well as increasing and diversifying the supply of food for home consumption.

Studies on the development of a commercial method for canning the blue crab of the Atlantic and Gulf coasts were continued with series of experimental packs of crab creole, crab gumbo, crab soup

(Norfolk style), crab cakes, and crab sandwich paste.

In addition, many experiments were made to prevent discoloration of crab meat packed without other food ingredients. Considerable progress has been made toward the solution of this latter problem, as packs have been prepared which show no discoloration after six months of storage and have the color and flavor of fresh crab meat. The method is now being tested on a large commercial scale at various fish-canning plants along the Atlantic and Gulf coasts and the results of this work will be reported upon later.

In addition to the above mentioned products, further experimental packs prepared during 1937 have included fish chowder, clam chowder, scallops, whiting, California pilchard (sardine), Dungeness crab, Maine sardine, and herring (alewife) roe. The results are not vet

The survey of present and modern commercial methods for the canning of fish and seafoods was continued. Field work was carried out in the Chesapeake and New England areas. Data were gathered on commercial methods of canning alewives and alewife roe, finnan haddie, fish balls, fish cakes, fish flakes, Atlantic mackerel, sturgeon. shad, soft clams, mussels, crab, lobster, Maine sardines, pet food, clam chowder, fish chowder, fish roe, anchovies, smoked herring, spiced herring, smoked salmon, salmon caviar, and salmon bait eggs.

At the request of the State of Virginia, our technologist in charge of experimental canning was detailed to make a study of the herring roe canning industry in that State, with a view to improving methods, and to draw up tentative grades and regulations for a State voluntary inspection system of canned herring roe. As a result of this work, a State inspection system is being set up for this purpose adopting recommendations made in this study.

## BACTERIOLOGICAL STUDIES

Our bacteriological investigations during the past year were carried on by Joseph F. Puncochar, junior bacteriologist; Harold E. Crowther, research associate; and Louis F. Ortenzio, graduate student assistant. Most of our bacteriological problems are closely integrated phases of specific problems or projects in the preservation of fishery products for food or the preservation of fishery byproducts, or closely coordinated studies of spoilage problems. Thus, bacteriological examinations are made of the experimental packs of canned fishery products to determine which processes produced sterility; bacterial counts are made on samples used in our studies on the development of indices of relative freshness or of decomposition; the use of ultraviolet rays in killing bacteria; determinations of the value of various chemical preservatives in preventing or retarding bacterial spoilage in fishery byproducts; and other miscellaneous bacterial control problems.

# STUDIES OF ULTRAVIOLET RAYS IN KILLING BACTERIA

Since the reduction of the presence of bacteria in fish is essential to the preservation of fish, any device or method which can be found to bring about this accomplishment is vitally important to the industry and to the consumer. According to information which we have received, resulting from studies made on other food products, the use of ultraviolet light rays has been beneficial in reducing bacteria in milk, meats, bread, etc., and in improving the keeping qualities of these foods. Therefore, late in 1937, our bacteriologists began a study of the effect of these ultraviolet rays in reducing the bacterial count of various fishery products. As a result, we have found that the rays will kill marine bacteria and we hope to work out a practical and commercially feasible application of this method in the treatment of fishery products.

STUDIES IN THE HANDLING OF FRESH OYSTERS

Late in 1937, at the request of the Oyster Institute of North America, and in cooperation with that organization, a program for studying the handling of fresh oysters was undertaken. Louis F. Ortenzio, a member of the Division's technological staff, was assigned to the study of this problem. While this problem has certain chemical aspects, the major portion of the investigation is a bacteriological one. The work has not progressed to a point where recommendations in the improved handling of oysters can be made.

Briefly, the following experimental procedure is being used. Bacterial counts to measure the rate of bacteriological decomposition and determinations of the pH to measure the rate of chemical decomposition are being made on commercial shipments of oysters. This may lead to the development of a test for determining the relative freshness of oysters as well as to the development of methods for preventing or

retarding spoilage of fresh and frozen oysters.

#### PHARMACOLOGICAL STUDIES

The role of minerals in foods and in feedstuffs for farm animals is becoming of increasing importance. Not only have certain minerals been found to be essential in nutrition, but there is need for a better understanding of other physiological effects they may have on the animal organism. With this in mind, the Bureau has continued its studies on certain minerals, naturally occurring in fishery products.

#### THE FLUORINE CONTENT OF FISHERY PRODUCTS

The fluorine content of foods presents a major problem in nutrition since the discovery that fluorine is responsible for mottled enamel of teeth. Therefore, during 1937, our technological staff undertook a

study of the fluorine content of various fishery products and the effect of this fluorine, as it naturally occurs in some fishery products, in the metabolism of the animal organism. A series of so-called "balance" experiments were started, in our College Park laboratories, to determine the intake and excretion of fluorine in rats fed a diet of canned fish, containing about 8 parts per million of fluorine. Preliminary work on this problem indicates that there were no apparent toxic symptoms in the experimental animals after a test period of 12 weeks, and the consumption of fish was very statisfactory.

#### MANUFACTURE OF FISHERY BYPRODUCTS

The utilization of waste for the manufacture of byproducts is becoming of increasing importance, probably more so in the fishery industries, than in other food industries. It has been estimated that the value of fishery byproducts represents about 15 percent of the total value of all fishery products in the United States. When we study the diversification of these byproducts and their uses, they loom into even greater economic importance than their relative volume would seem to indi-Fishery byproducts furnish raw materials or finished products for such highly important consuming industries as the drug, paint and varnish, soap, and feed industries. Accordingly, our technologists are giving increasing attention to the conversion of fish waste and other waste materials resulting from our fishery harvest into useful byproducts. During 1937, investigations dealing with the preservation of fishery byproducts were carried on in the Seattle technological laboratory under the supervision of Roger W. Harrison, technologist in charge, with the assistance of Andrew W. Anderson, assistant technologist (subsequently transferred to the market news service); Robert E. Silver, junior chemist; and Leslie Lowen, Neil Nellis, and Robert Rucker, research associates and student assistants; and in our College Park technological laboratory under the supervision of of James M. Lemon, technologist in charge, with the assistance of S. R. Pottinger, junior technologist; M. E. Stansby, junior chemist; Joseph F. Puncochar, junior bacteriologist; and Harold E. Crowther, R. H. Flowers, and C. E. Swift, research associates and student assistants.

## UTILIZATION OF SALMON-CANNERY TRIMMINGS

In previous reports we have discussed the economic importance of the waste accumulated during the preparation of salmon for canning and the progress being made in the Bureau's studies on methods of utilization. During 1937, we had hoped to extend this work to pilot plant operations but due to unforeseen delays in getting the new technological laboratory building in Seattle, Wash., in readiness such studies were necessarily postponed and the investigation was confined to work permitted by the facilities of the chemical laboratories.

In view of this, a rather extensive survey was made on the chemical and physical properties of the oil obtainable from the various components of salmon waste and from the total waste of the five species of salmon from the principal fishing areas of this fish in the United States and Alaska. As indicated in our last report, it is possible to obtain oils having quite widely varying properties. The chemical studies on these samples were continued during the past year for the

purpose of obtaining further data on their composition. The studies included the estimation of the percentages of saturated and unsaturated fatty acids and their mean molecular weights. These data

are being included with the former data in report form.

In certain localities in Alaska the problem of utilizing salmon cannery trimmings is primarily one of how to overcome the seemingly prohibitive situation of having a season of operation of not more than 30 days during the year. One means of accomplishing this would be to broaden the scope of operations to include other types of fish which are available over a longer period of time which would permit a byproducts plant to operate over a longer season. In this connection our technologists began studies on the utility of other fishery materials which might be available for supplementing the supply of salmon cannery waste. An examination of samples of atkafish, said to be abundant in the Bristol Bay area, indicated these fish would yield at least 30 gallons of oil per ton of raw material and the resultant meal would contain over 70 percent protein. Except for color, the properties of atkafish oil were quite similar to those for red salmon oil. Greater attention might also be given to the utility of these fish as a source of human food.

Since beginning our investigations on the utilization of salmon cannery waste, definite progress has been made by the salmon-canning industry toward more complete use of the waste. A certain degree of this progress can be attributed to the advisory service being supplied by the Bureau's technologists on the basis of their investigational work.

# FISH-LIVER OIL STUDIES

Methods of extraction.—Because of the sustained interest in fish livers as sources of highly potent vitamin active oils, the Bureau has continued to give considerable attention to developing methods for

the more economical extraction of oil from these livers.

In last year's report reference was made to the development of a simple method of oil extraction which had been demonstrated to be applicable to halibut and "lingcod" livers. This involved a special mechanical disintegration of the liver, conversion of the liver tissue into a soluble and nonheat coagulable condition, and separation of the oil from the solution by centrifuging. An application for a public service patent on the method is on file at the United States Patent Office.

During the past year the above method of extraction was found to give satisfactory results with swordfish livers but was not directly applicable with uniform success to domestic tuna livers. This is because the tuna livers are normally of very low oil content and the active lipolytic action in the liver during the period required to bring the catch to port results in there being only a very small quantity of neutral glyceride oil available for recovery. This difficulty, however, can be overcome by mixing a quantity of foreign oil with the livers prior to subjecting them to the extraction process. Experiments on salmon livers and salmon waste during 1933 had demonstrated the vitamin solvent action of fish oil and the experiments on tuna livers during the past year demonstrated the increased efficiency when using the foreign oil in connection with the process developed for halibut livers. The method is applicable for producing oils

approaching the normal concentration of the oil in the liver or it may be used in fortifying the foreign oil to any desired degree below this

potency.

Vitamin testing methods.—For a number of years the antimony trichloride color reaction has been a popular method for estimating the vitamin A potency of fish-liver oils and finds usage as a control test. However, the method has been subjected to such a great amount of criticism that many investigators consider the test to carry no degree of reliability. In spite of this criticism, there are others who have found the method useful and continue to use it, taking cognizance of its reported limitations. One of the principal criticisms of the method is that there is no consistent relationship between Blue value (colorimetric method) and Biological value as determined with rats. In this case, however, the data are generally viewed from the standpoint of a direct comparison.

During the course of our liver oil studies, Blue unit values have been obtained on a relatively large number of liver oil samples having vitamin A potencies varying between 5,000 and 200,000 U. S. P. units per gram as determined by biological assay. In studying these data, there was found to be a definite power relationship between the two types of values. In applying this correction it has been possible to

increase the accuracy of the test.

#### FISH OILS IN PAINTS

During the past year, as a result of conferences of our technologists with members of the industry, there was a greatly increased use of fish oils in paints. Not only did this increase extend to the lower grades of paints, but, for the first time in the history of the paint industry, some of the leading paint manufacturers made extensive use of fish oils as ingredients of the higher priced paints and this fact was widely advertised in trade journals. This development can be attributed largely to improvements in the refining of fish oils by some of the leading refiners of the country, with the cooperation and assistance of our technologists.

## STUDIES ON FAT IN FISH MEAL

As fish meals have become more widely used and their properties more thoroughly understood, the question of fat content has likewise become an important consideration. The reason for this is that the amount of fat present is an indication of the proportion of the material which may be subject to oxidative deterioration. Consequently, low fat content meals are preferred by some consumers and sale may be predicated upon this factor. Unfortunately, however, the fat, or more correctly the oil, becomes less soluble in normal solvents when oxidized, and oxidation may, therefore, lead to an apparent decrease in fat content. Furthermore, accepted practice for determining fat is not uniform. The unsatisfactory nature of this situation is obvious because a meal reported as having a low solvent extract value may have reached this condition as a result of oxidative deterioration.

For some time the Bureau has appreciated the need for tests which will clarify this confusing condition, because such information would not only lead to more satisfactory methods of control in marketing fish meal but would also provide useful means in furthering study of changes taking place during storage and the effectiveness of improved

storage practice.

During the past year attention has been given to determining the relative amounts of extractable material removed by different solvents from fish meal soon after being prepared and after extended storage under conditions known to lead to oxidative deterioration. Sixteen solvents were tested on two separate types of fish meal. The most significant aspect of the data secured on these tests illustrated the widely differing effectiveness of individual solvents and the fact that effectiveness is closely related to chemical structure. This will materially facilitate the work contemplated during the ensuing year.

In addition to the studies mentioned above, which were conducted in the Seattle laboratory, the Bureau's nutrition laboratory at College Park, Md., has been studying the physiological effect of the development of rancidity or oxidative deterioration in the fat of various fish meals, and other chemical changes, in the feeding of both white rats and baby chicks, as laboratory animals. This latter investigation particularly emphasizes the effect on these animals of any physiological and chemical changes which may be induced under varying conditions of manufacture, handling, and storage, which may cause the development of rancidity of the fat or the partial digestion of the protein in these fish meals. These studies have not progressed to a point where any conclusions can be reported.

#### CHEMICAL PRESERVATION OF FISH AND FISH WASTE

Several years ago the Bureau established a cooperative arrangement with the Aquacide Co., Washington, D. C., for the conduct in the Bureau's College Park technological laboratories of a study of methods of chemical preservation of fish and fish waste. At many points in the United States and in Alaska there are relatively small accumulations of fish waste or waste fish, not sufficient to justify the installation of machinery or mechanical equipment for the production of byproducts, but sufficiently large to merit the development of cheaper methods of utilization. The problem has been attacked from two standpoints. One is the temporary chemical preservation of the waste until it can be transported to some central point for more complete mechanical reduction and the other is outright chemical

preservation or reduction for use as fertilizer stock, etc.

As in 1935 and 1936, the Aquacide Co., during 1937, employed and stationed in our laboratories Harold E. Crowther, R. H. Flowers and C. E. Swift, research associates. Already, results of considerable practical value have evolved from this program of cooperative research. A chemical solution developed by the above company has been tested on various types of fishery waste and has been shown to be very effective in its preservative qualities. In recent years its effectiveness has been improved by numerous tests on fishery waste. One very important commercial possibility, as a result of this work, is the temporary chemical preservation of cod livers and other fish livers at sea until these livers can be transported to a central plant for the extraction of the oil. The widespread application of this method has promise of saving from spoilage many fish livers which now do not reach the plant quickly enough for the extraction of an oil of good

quality. At the present time only a relatively small part of the catch of haddock and cod is made close to shore, and for this reason the method may find use as a temporary means of preservation for

the livers yielded by the fisheries for these species.

During 1937 one of the research associates working on the chemical preservation of fish waste was stationed at Boston, Mass., to direct the handling and preservation of fish livers at sea. Under his direction many types of chemical preservatives were tested under practical The preservative solutions were sent to sea on fishing vessels and fresh livers were placed in these solutions by the fishermen. The livers were then shipped to the Bureau's College Park laboratories, where they were inspected, rendered, and the relative quality of the oils determined. By these experiments there was developed a very effective preservative chemical solution which stopped bacterial and enzymatic decomposition and kept the oils in their original fresh However, rendering methods in ordinary commercial use were not easily adapted to these preserved livers. Therefore, a new "flotation" process was developed which results in high yields of oil, oils of high quality, and economy of operation. The details for large scale application for these preservative and rendering processes are now worked out on a semicommercial basis and the commercial usefulness of the work seems assured.

As a part of this cooperative program our nutrition laboratory is making an extensive study of the vitamin A and D content of the various organs of the viscera of cod, cusk, hake, halibut, haddock, pollock, and other species preserved with the chemical formulas.

#### NUTRITIVE VALUE OF AQUATIC PRODUCTS

There is a great need for more complete information concerning the food value of various commercially important fishery products. There is also considerable demand for this information, not only from the industry, but from the consuming public. There are notable gaps in this information because scientific studies have not covered all of these fishery products, and there is only partial knowledge of the nutritional properties of some of the others. The lack of this information hinders dietitians and home economics experts in determining the most satisfactory use of fishery products in the diet. The food and drug industries need, and have requested, information on the nutritive value of aquatic products. The feed manufacturer and the farmer require more complete data on the qualities of fishery products for animal feeding. Therefore, it is highly important that our technological staff obtain, as soon as possible, more complete information on this subject, and at least fill in the important gaps in scientific knowledge concerning the unexcelled nutritional value of these products of the sea.

Furthermore, nutrition studies are necessary to properly evaluate our technological investigations on the improvement of existing methods and the design of new methods in the handling, utilization, processing, preservation, and storage of the great diversity of prod-

ucts of the fishery industries.

During 1937 investigations concerning the nutritive value of fishery products and byproducts were conducted in our College Park laboratories under the supervision of James M. Lemon, technologist in charge,

by Dr. Hugo W. Nilson, assistant pharmacologist; S. R. Pottinger, junior technologist; Charles F. Lee, junior chemist; William B. Lanham, Jr., junior chemist; Joseph F. Puncochar, junior bacteriologist; and Willis H. Baldwin and Hillman C. Harris, graduate student assistants, with the cooperation of Professor M. H. Berry of the Dairy Department, Maryland State Agricultural Experiment Station; and in our Seattle laboratory under the supervision of Roger W. Harrison, technologist in charge, assisted by Charles Butler, William Clegg, Louis Simenson, Marie Sater, and Rhea Waterberry, chemists, assigned to our laboratory by the Works Progress Administration; and with the cooperation of Dr. J. S. Carver, Washington State College, Pullman, Wash.

#### VITAMIN CONTENT OF FISHERY PRODUCTS

As in former years, our nutrition laboratory continued assays of numerous samples of fish oils and fish-liver oils from different species for content of vitamins A and D, prepared experimentally in connection with the byproducts program of our Seattle laboratory. We also began, in cooperation with the Federated Scallop Producers Cooperative Association, determinations of vitamins A and D in scallop waste, but we had to discontinue this work before it was completed because the association and the scallop industry failed to continue its support in supplying samples in accordance with the laboratory schedule. However, preliminary studies indicated a higher vitamin A potency in scallop waste than we have found in the flesh of other species of fish or shellfish previously analyzed.

In a previous section in this report, some studies were discussed which were started in 1937 in connection with the use of ultraviolet rays in killing bacteria in fish. In addition to the value of these rays in reducing the bacterial count in fish so treated, preliminary analyses by the nutrition laboratory showed that the irradiation of haddock fillets by this mercury vapor lamp increased the vitamin D potency of the samples. If more complete data or further studies in this connection substantiate these conclusions, this discovery will have considerable commercial significance, as fish fillets or other edible portions of fish could be irradiated in the same manner as milk is now treated

and sold by dairies at a premium as "vitamin D milk."

Recent discoveries in the chemistry of vitamins have shown that the substance which chemists originally classified under the term, "vitamin B," is really a combination of vitamins. This combination or substance is now known as the vitamin B complex. Newer knowledge of vitamins, being obtained by scientists every day, is gradually identifying the vitamins which make up this complex. This means that the interpretations of the results of nearly all of the previous analyses of vitamin B and vitamin G, which formerly was classed with vitamin B in fishery products and in other foods, must be modified in accordance with these more recent discoveries. Therefore, the Bureau's nutrition laboratory has found it necessary to devote a limited amount of time to the development or standardization of new methods of analysis for these vitamins, constituting the vitamin B complex, for application to fishery products. Studies of the vitamin B complex in oysters and in three types of canned salmon have been begun.

#### CHEMICAL COMPOSITION AND NUTRITIVE VALUE OF FISH PROTEINS

As was discussed in last year's report, technologists in the College Park laboratory began, during the latter part of 1935, a study of the composition and nutritive value of proteins in some of the commercially important species of fish and shellfish. This information has been desired by welfare authorities, physicians, dietitians, and others interested in nutrition and health. Protein, which is the basis of all diets of man and his domestic animals, is a very complex chemical compound and varies in biological or nutritive value according to its composition. To date our technologists have isolated and determined the amounts of cystine, tryptophane, arginine, histidine, and lysine in cod, haddock, sea herring, Boston mackerel, Spanish mackerel, croaker, mullet, shad, red snapper, halibut, lake trout, oysters, crabs, clams, and shrimp. In feeding experiments with laboratory animals, it was found that fish proteins were at least 90 percent digestible. was also found that the proteins from fishery products were definitely superior to both casein and beef in promoting growth in the experimental animals, when fed in a diet in which the protein was a limiting

The concentrates, extracted from the various species of fish and shellfish mentioned above, constitute a highly nutritious and attractive flour or meal which consists of about 95 percent protein and 3 percent mineral constituents. As it is almost a pure protein, it should have great possibilities as an ingredient of baby and invalid foods. Likewise, it should be well suited for making such bakery products as cookies and crackers. These concentrates could be made on a commercial scale from many species of fish, not now finding a ready sale, as well as from the edible trimmings of our common market fishes.

#### MINERAL CONSTITUENTS OF FISHERY PRODUCTS AND BYPRODUCTS

As has been stated previously, the mineral constituents of foods are being shown to be of increasing importance as the science of nutrition progresses. About 34 mineral elements have been identified in sea water, and nearly all of them have been found, in traces at least, in aquatic products. Among the minerals which have been shown to be of great importance in nutrition are calcium, phosphorus, iodine, copper, iron, manganese, and magnesium. In general, fishery products are excellent sources of these mineral constituents and superior sources of some of them, such as iodine. In order to determine the relative standing of various fishery products in these minerals, detailed analyses were made, during 1937, of the kinds and quantities of these mineral constituents in cod, haddock, mackerel, salmon (canned), shrimp, crab meat, and oysters.

# FISH MEAL IN ANIMAL FEEDING

The Bureau's cooperative experiments with the Department of Poultry Husbandry at Washington State College, Pullman, Wash., were continued during the past year. This work has been concerned largely with the vitamin content of fish meals.

In earlier studies evidence was obtained indicating the practicability of producing fish meals containing sufficient vitamin D to

supply an adequate amount of this vitamin to the ration when the meals are included in normal quantity. In the present work attention is being given to the matter of vitamin retention, since the utility of fish meals must be based on their quality when fed, and this

may mean after storage periods up to and exceeding 1 year.

The principal problem in storing meals containing any appreciable quantity of oil is to prevent oxidation changes in the oil which lead to the formation of undesirable rancid products and cause vitamin destruction. The investigation during the past year was designed to study the effect of cereal flours as antioxidants when incorporated with the meal during storage. The experimental samples, however, carried a much higher vitamin content than was anticipated and a proper level of diet was not determined during the time allowed for this particular work. The experiments are being repeated during the present year, and, in addition, attention is being given to the effectiveness of pelleting as a means of preventing deterioration during storage. When the meal is compressed into pellet form the tremendous surface exposed by the finely ground material is drastically reduced, air is excluded and only a limited opportunity for oxidation is permitted.

#### KELP MEAL IN ANIMAL FEEDING

One of the principal problems of the modern dairy industry, according to animal husbandrymen, is the irregularity in the reproductive capacity of dairy cows. Workers in dairy science have been looking for some means to arrest this condition through improvements in the ration of the dairy herd. Since it has been known for some time that certain minerals influence reproduction and lactation, in their search for dietary solution, the attention of dairy husbandrymen has been directed to so-called mineral feed supplements. Kelp meal, a dried and finely ground product of the giant kelp, a species of seaweed of the Pacific coast, is known to be an excellent organic source of certain minerals which have nutritional value. Dr. McCollum, of Johns Hopkins University, has shown that magnesium and manganese are important in reproduction and lactation in such laboratory test animals as white rats. Kelp meal is an excellent source of these two minerals. Therefore, during the past year, in cooperation with our technologists, Professor M. H. Berry, of the Dairy Department, Maryland State Agricultural Experiment Station, College Park, Md., inaugurated a series of feeding tests with dairy animals to determine whether the addition of kelp meal to these experimental rations would have any value in improving reproduction in dairy cattle. Because of the nature of the experiments and the time element involved, it is expected that at least 3 years will be required to obtain results on which any conclusions can be based.

#### FISH COOKERY STUDIES AND DEMONSTRATIONS

As stated previously in this report, there has been a great increase in interest on the part of dietitians, home economics workers, and others, in the nutritive value of fishery products and their importance in the diet of the American people. From this, it would naturally be expected that there would be a great need and a great demand for information on fish cookery. Therefore, during 1937, Agnes I. Web-

ster, of the Division's staff, continued her studies and practical demonstrations of fish cookery recipes. In addition to the developing and testing of new recipes in our fish cookery laboratory, Miss Webster also conducted practical demonstrations before home economics workers, housewives, etc., in New Brunswick, N. J.; Baltimore, Md.; and various points in the State of Florida.

During 1937, the Federal Surplus Commodities Corporation purphend of applicable quantity of surplus fish for literal testing to

chased a considerable quantity of surplus fish for distribution to persons on relief rolls in various parts of the country. In connection with the distribution of these fish, Miss Webster conducted practical demonstrations in fish cookery before relief workers, and others interested, at various points in the Midwest.

#### RESEARCH ASSOCIATES AND STUDENT ASSISTANTS

Because of the relatively small size of the Bureau's technological staff, and the rather broad field of research it must cover, it is only possible to undertake those problems which are of a fundamental nature and which promise to be of the greatest value to the largest number of persons, whose livelihood depends in whole or in part on the fisheries, and which are possible with the funds and personnel available. For this reason the Division cannot, with present facilities, attack problems of special or restricted interest affecting certain products, processes, methods, or industries. However, the Bureau has available, by congressional authorization and under an arrangement similar to that of other scientific Government bureaus, facilities for research associates and student assistants in its laboratories. salaries and expenses of these employees are paid by the firms or groups who are interested in the problems on which they are working and the investigations are carried out under the supervision of the Bureau's technologists in its laboratories and under its control. the Bureau provides these industries and groups with laboratory, consulting, and library facilities which, in most instances, cannot be obtained elsewhere.

Within the limits of its facilities, the Bureau also has opened its technological laboratories to research students who are pursuing courses in universities and who are selecting investigational problems in the fisheries as their major study. This may prove of special benefit to the industry as it brings its problems to the attention of a large group of research workers who in turn may spread interest to applied fishery

research.

The following research associates and student assistants carried on investigations under the supervision of our technological staff during

the past year:

In the College Park Laboratory, C. E. Swift, research associate, employed by the Musher Foundation, Inc., New York City, working on the problem of rancidity in fishery products and byproducts; Harold E. Crowther, R. H. Flowers, and C. E. Swift, research associates, employed by the Aquacide Co., Washington, D. C., working on problems in the chemical preservation of fishery byproducts; William B. Lanham, Jr. (part of the year), Willis H. Baldwin, Hillman C. Harris, and Louis F. Ortenzio, part-time graduate student assistants, employed by the Bureau of Fisheries and working on problems in the chemistry and metabolism of fish products, lactic acid as an index of decomposition in fish, and in the handling of fresh oysters; Ned Oakley and Roscoe Dwiggins, student assistants provided by the National Youth

Administration through the University of Maryland.

In the Seattle technological laboratory, Leslie Lowen, research associate, employed by the Musher Foundation, Inc., New York City, working on the problem of rancidity in fishery products and byproducts; and Neil Nellis and Robert Rucker, student assistants provided by the National Youth Administration through the University of Washington.

The details of the above work has been described in the preceding

pages.

# EDUCATIONAL AND CONSULTING SERVICE

In addition to the research activities described in this report, our economic and technological staffs conduct, along with their regular duties, an educational and consulting service for those interested in the During the past year the demand for this type of service has increased. Many requests have been received from groups and individuals to demonstrate improved methods developed in our laboratories for the handling and processing of fishery products, for instruction in fish cookery, and for aid in improving various marketing practices. Insofar as our facilities have permitted, we have complied with these requests, endeavoring to offer assistance especially where the request has come from a large group or industry. However, we have not been able to comply with all of the requests received because of insufficient personnel and because of inadequate funds to provide for the travel expenses of the demonstrators.

Some of the educational services rendered are discussed or referred to in previous paragraphs of this report. In brief, this work has covered the fields of commercial preserving of fishery products, fish cook-

ery in the home, and the marketing of aquatic products.

Another phase of this service has consisted in answering thousands of letters directed to the Bureau on fishery subjects and in supplying information to persons who have called at the Bureau personally. Many of the latter came from foreign lands to seek fishery information which might be useful in the conduct of the industry in their native country.

PUBLICATIONS OF THE DIVISION

During the calendar year 1937 the following publications were pre-pared and addresses delivered by members of the Division's staff. These do not include the monthly statistical bulletins of the landings of fishery products at Boston and Gloucester, Mass., Portland, Maine, and Seattle, Wash., nor the monthly reports on cold-storage holdings of frozen fish and quantities of fish frozen. The fishery reports and circulars may be purchased, at the prices shown, from the Superintendent of Documents, Government Printing Office, Washington, D. C. The statistical bulletins and special or S-memoranda are distributed free of charge upon request to the Bureau. The special articles may be obtained from the sources of publication.

Those wishing to receive copies of this report, and statistical bulletins as issued should request that their names be placed on the Bureau's mailing lists, Nos. 128 for the annual statistical report; 128a for general statistical bulletins; and 128b for monthly cold-storage reports. Those desiring historical statistical data on the domestic fisheries for the period 1880 to 1929 should consult the report entitled "Fishery Industries of the United States, 1930," by R. H. Fiedler, appendix II to the Report of the United States Commissioner of Fisheries for the fiscal year 1931. Statistical information for the years 1930 to 1935, inclusive, may be obtained from the annual reports of the Division for the years 1931 to 1936, inclusive.

Fishery products landed by United States vessels at Seattle, Wash., 1936. Statistical Bulletin No. 1233.

# Part 2. FISHERY STATISTICS, 1936

## GENERAL REVIEW

Based upon available statistics for 1936, there was a large increase in the catch of fishery products in the United States and Alaska as compared with that of the preceding year. Statistics of the catch were collected for both 1935 and 1936 in the Chesapeake, Pacific, and Lake States and in Alaska, and, when considering the combined catch of these sections alone, an increase of 22 percent in the volume and 19 percent in the value of the catch is indicated. While these increases are reflected in each of the four geographical sections and in many species, they are especially important in increased catches of pilchard in California, and salmon in Alaska. The value of the production of canned fishery products in all sections increased 26 percent as compared with 1935; byproducts increased 17 percent; frozen fish about 1 percent; and packaged fish 6 percent.

The total catch of fishery products in the United States and Alaska as based on the most recent surveys, amounted to 4,840,299,000 pounds, valued at \$92,823,000. About 129,000 fishermen were

employed in making this catch.

In 1936 in the United States and Alaska, the production of canned fishery products amounted to 794,707,014 pounds, valued at \$94,564,254; the output of byproducts was valued at \$34,976,347; and production of frozen fishery products, excluding packaged products, amounted to 106,679,695 pounds, estimated to be valued at \$8,700,000. Based on the most recent surveys the production of cured fishery products amounted to 116,310,859 pounds, valued at \$15,615,682, and fresh and frozen packaged fish and shellfish, 202,395,954 pounds, valued at \$26,894,905. It is estimated that about 680,000,000 pounds of fresh fishery products (excluding fresh packaged fish and shellfish), valued at about \$55,000,000, were marketed during 1936. The total marketed value to domestic primary handlers of all fishery products in 1936 is estimated at \$236,000,000.

Fishery products imported for consumption were valued at \$41,-

872,560 and domestic exports were valued at \$13,214,166.

New England States.—No survey for the entire catch of fishery products in these States was made for 1936. In 1935 both the volume and value of the catch showed an increase as compared with 1933, when the first preceding survey of the complete catch was made. There were increases in both the volume and value of the combined

landings of fishery products by vessels at Boston and Gloucester, Mass., and Portland, Maine, and a large increase in the production

of Maine sardines in 1936 as compared with 1935.

Middle Atlantic States.—No complete survey for the catch of fishery products in these States was made for 1936. In 1935 there was a large increase in both volume and value of the catch as compared with the catch in 1933, when the first previous survey was made. There was a large increase in the production of frozen fish and in the catch of shad in the Hudson River in 1936 as compared with 1935.

Chesapeake Bay States.—In 1936 the catch of fishery products in the Chesapeake Bay States increased in both volume and value as compared with the preceding year. The value of the menhaden products, which were produced in Virginia, increased appreciably; however, the production of fresh-shucked oysters and packaged

fresh-cooked crab meat decreased.

South Atlantic and Gulf States.—The catch of fishery products in the South Atlantic and Gulf States during 1936 showed large increases in both volume and value over 1934, when the first preceding survey of the catch was made. There was a large increase in the volume and value of packaged fresh-cooked crab meat in 1936 as compared with 1934. The output of canned shrimp and oysters in 1936 showed only slight variation from the production in 1935.

Pacific Coast States.—The commercial catch of fishery products in these States for 1936 was the largest of any year on record and the value of the catch exceeded that of any previous year except 1929. The increased volume of the catch was largely accounted for by the record catch of pilchards in California. The 1936 production of canned sardines, tuna, and oysters increased as compared with 1935

while the packs of mackerel and salmon decreased.

Lake States.—In 1936 the commercial catch of fishery products in the Lake States increased in both volume and value as compared with 1935. The catch of blue pike was the largest on record, while that

of yellow perch was below normal.

Mississippi River and tributaries.—The most recent complete statistics of the catch of the Mississippi River and tributaries are those collected for 1931. As compared with 1922, when the most recent preceding survey was made, there was a decrease in the catch. This decrease was reflected principally in a smaller catch of fresh-water mussels. A survey made for Lakes Pepin and Keokuk and the Mississippi River between these two lakes showed an increase in 1936 for the catch for Lake Keokuk and the river between the lakes, but a decrease in the figures for Lake Pepin. The production of fresh-water mussel-shell buttons increased in 1936 as compared with 1935.

Alaska.—The catch of fishery products in Alaska in 1936 increased in both volume and value as compared with 1935, and the pack of canned salmon was the largest in history. The production of fresh and frozen fishery products increased while that of byproducts and

cured products decreased.

Included in vessels.

<sup>2</sup> Includes scows, houseboats, pile drivers, etc.

3 Statistics not available.

Includes packaged, cured, and canned fishery products, and byproducts. Includes data for 1936 on packaged and canned products and byproducts.

Note.—Of the total number of persons engaged in the preparation of fishermen's manufactured products,  $\mathbf{6.203}$  have also been included as fishermen, and 1.235 of the persons shown on transporting craft have also been included as fishermen.

### MANUFACTURED FISHERY PRODUCTS

The output of manufactured fishery products (canned, cured, packaged, and byproducts) in the United States and Alaska during the most recent years for which data are available were valued at \$172,-Of this amount, canned products accounted for 55 per-051,188. cent, byproducts 20 percent, fresh and frozen packaged products 16 percent, and cured products 9 percent.

Since general statistical surveys were conducted in only the Chesapeake Bay, South Atlantic, Gulf, Lakes, and Pacific States, and Alaska for 1936, the following compilation of manufactured fishery products consists of composite data, based on the most recent statistics.

years covered by the data are indicated by footnotes.

8 This item represents a combination of 1935 and 1931 data.

Includes fresh filets of amberjack, bluefish, catfish and bullheads, jewfish, kingfish or "king mackerel," king whiting or "kingfish," mullet, scup or porgy, sea robin, snook or sergeantfish, spot, suckers, tripletail, tullibees, and whiting

10 Includes frozen fillets of bluefish, halibut, lake herring, and squeteagues or "sea trout."

11 Includes fresh steaks of cabio, cod, haddock, halibut, pollock, sea bass (Atlantic coast), and snook or sergeantfish.

12 Includes frozen steaks of cod, pollock, and wolffish; packaged fresh-cooked spiny lobster meat; and

fresh-shucked sea mussels.

13 Includes salted barracuda, bluefish, blue runner, chubs, cod strips and bits, haddock, salmon bellies, sea

- <sup>13</sup> Includes satted barracuda, bluefish, blue runner, chubs, cod strips and bits, haddock, salmon beliles, sea herring, black sea bass, pilchard, tenpounder, tuna, and yellowtail; tighte roe; boneless cusk, mild-cured shad; pickled shrimp; and salted fillets of hake, sea herring, and Spanish mackerel.
  <sup>14</sup> Includes smoked bluefish, cod, red drum, flounders, goldfish, goosefish, haddock, smelt, swordfish, tuna, fillets of haddock and sea herring, sea herring roe, and spiced salmon.
  <sup>15</sup> Includes canned Alaska salted cod, pickled eels, finnan haddie, smoked salmon, kippered sturgeon, fresh-water crawfish, shrimp soup, hard clams steamed in the shell, hard clam stew, soft clam cakes, coquina clam broth, pickled sea mussels, frogs and frog legs, deep sea roe, rat poison bait, fish paste and bouillon, and crab and shrimn gumbo. crab and shrimp gumbo.
  - 16 Includes sea herring and groundfish (white fish), dry scrap, and miscellaneous acid and dry scrap. 18 Includes burbot, tullibee, salmonegg, abalone, soft clam, cod-liver, and miscellaneous fish meals.

    18 Includes burbot, halibut-, "lingcod-," sablefish-, swordfish-, totuava-, and tuna-liver oils.

    19 Includes rosefish and miscellaneous fish oils.

<sup>20</sup> Includes isinglass, kelp products, pearl essence, shark skins, and fresh-water mussel-shell novelties, stucco, and chips.

-Some of the above products have been manufactured from products imported from another country; therefore, they cannot be correlated directly with the catch within the United States and Alaska.

### CANNED FISHERY PRODUCTS AND BYPRODUCTS TRADE

The output of canned fishery products and byproducts in the United States and Alaska in 1936 was valued at \$129,533,238. Of this total. canned products comprised \$94,564,254, and byproducts, \$34,968,-984—an increase of 26 percent in the value of canned products and 18 percent in the value of byproducts when compared with the respective values of the same groups of commodities for the previous vear.

Fishery products were canned at 412 establishments in the United States and Alaska during 1936. The combined output of these canneries amounted to 20,097,976 standard cases. The net weight of the products canned amounted to 794,707,014 pounds.

Canned fishery products or byproducts were prepared in 25 States and in Alaska during 1936. Alaska ranked first in the value of the products, accounting for 36 percent of the total, and California ranked

second, with 31 percent.

<sup>2</sup> This is usually an intermediate product and although shown in the total may also be shown in its final stage of processing elsewhere in the table.

<sup>33</sup> Includes the production of burbot-liver oil in Minnesota and Wisconsin.

<sup>32</sup> Of this production 34,834 tons, valued at \$1,148,416, were reported as dry scrap and 7,577 tons, valued at \$263,294, as fish meal.

Note.—The menhaden factories were located as follows: 1 in New York, 2 in New Jersey, 2 in Delaware, 10 in Virginia, 8 in North Carolina, 1 in Georgia, and 5 in Florida.

Includes the production of burbot-liver oil in Minnesota and Wisconsin.
 Includes groundfish, herring, and miscellaneous acid and dry scrap.
 Includes salmon-egg, abalone, clam and miscellaneous meals, and cod-liver pressings.
 Includes a considerable production of salmon oil especially prepared for human consumption.
 Includes burbot, halibut, "lingcod," sablefish, swordfish, totuava, and tuna-liver oils.
 Includes rosefish and miscellaneous fish oils.
 A guarative of livering clause of the production.

<sup>39</sup> A quantity of liquid glue produced by one firm in California is included with the production of liquid glue of the Atlantic and Gulf coasts. 40 Includes isinglass, shark skins, kelp products, and pearl essence.

### FROZEN-FISH TRADE 3

### FISH FROZEN

During 1936 the freezing plants which reported their activities to the Government froze 179,273,698 pounds of fishery products. These products at the time they were held in cold storage plants, were estimated to be valued at about \$15,000,000. Compared with the output in 1935 this was an increase of 20 percent in volume. Five species or groups of species accounted for 64 percent of the total amount frozen. In the order of their importance they were cod, haddock, hake, and pollock (including cod, haddock, and pollock fillets), which accounted for 27 percent of the total; whiting, 16 percent; halibut, 9 percent; salmon, 7 percent; and mackerel, 5 percent. Other products frozen in considerable quantities during the year were sea herring and shellfish.

<sup>&</sup>lt;sup>2</sup> New England includes the 6 States of that section: Middle Atlantic—New York, New Jersey, and Pennsylvania; South Atlantic—Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida; North Central, East—Ohio, Indiana, Illinois, Michigan, and Wisconsin; North Central, West—Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas; South Central—Kentucky, Tennessee, Alabama, Mississippi, Louisiana, Texas, Oklahoma, and Arkansas; and Pacific—Washington, Oregon, California, and Alaska.

### HOLDINGS

During 1936 monthly holdings of frozen fish and shellfish averaged 61,990,000 pounds, which is an increase of 19 percent as compared with the average monthly holdings in 1935. The largest supplies were in storage in December when 94,695,000 pounds were on hand and the smallest quantity was in storage in April when 26,102,000 pounds were held. The holdings during each of the months from September to December exceeded 84,000,000 pounds.

<sup>3</sup> Includes a small amount of fish held in Colorado in the Mountain section.

### COLD-STORAGE HOLDINGS OF CURED FISH

During 1936 monthly cold-storage holdings of cured herring and mild-cured salmon averaged 21,499,000 pounds which is an increase of 67 percent as compared with the average monthly holdings in 1935. The holdings during October were the largest, amounting to 30,666,265 pounds, and the smallest were in February, amounting to 14,417,137 pounds.

### FOREIGN FISHERY TRADE

The foreign trade in fishery products of the United States in 1936 amounted to \$55,086,726, of which \$41,872,560 represents the value of these products imported for consumption, and \$13,214,166, the value of exports of domestic fishery products. Compared with the previous year, there was an increase of 9 percent in total trade, and 16 percent in the value of the imports, but a decrease of 8 percent in the value of exports.

Imports consisted of 371,205,567 pounds of edible products, valued at \$30,356,439, and nonedible products, valued at \$11,516,121. Fishery exports consisted of 111,259,302 pounds of edible products, valued at \$12,262,784, and nonedible products, valued at \$951,382.

Import duties levied on fishery products imported during 1936 totaled \$6,544,971.

### FISHERIES OF THE NEW ENGLAND STATES

(Area XXII) 4

The most recent complete fishery statistics for the New England States (Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut) are those collected for the year 1935. In that year the yield of the commercial fisheries amounted to 655,430,400 pounds, valued at \$17,983,594 to the fishermen, representing an increase of 31 percent in volume, and 33 percent in value as compared with the catch in 1933, the most recent previous year for which statistics are available. Detailed statistics of these fisheries for 1935 appear in "Fishery Industries of the United States, 1936," appendix I to the Report of the United States Commissioner of Fisheries, 1937. A summary of these fisheries as well as statistics of the vessel fisheries at the principal New England ports for 1936 and the mackerel fishery of the Atlantic coast for 1936 appear in the following tables.

Fisheries of the New England States, 1935

OPERATING UNITS: BY STATES

Boats: Motor Other Accessory boats Apparatus: Purse seines:	2, 321 1, 737 183	43 28	1, 374 1, 666 562	460 666 86	259 526 26	4, 457 4, 623 857
Mackerel	26 5, 075		74 34, 395	300		101 39, 770

<sup>4</sup> This is the number given this area by the North American Council on Fishery Investigations. It should be explained that there are included under this area craft whose principal fishing ports are in the area but at times fish elsewhere. Notable examples are the groundfish fishery in area XXI and the mackerel and southern trawl fisheries in area XXIII. For a clearer understanding of the statistics published in this section, the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

1 Excluding seed oyster fishery. The seed oyster fishery in this section was prosecuted in Rhode Island and Connecticut where 167 fishermen, using 28 vessels, 1 motorboat, 15 other boats, 16 dreedges, and 7 tongs, took 106,243 bushels of seed oysters, valued at \$42,600, from public beds, and 376,568 bushels, valued at \$175,934 from private beds. Of the total number of persons, 18 are duplicated among those fishing for market oysters or other species. Similarly the following craft and gear are duplicated: 2 vessels, 4 dredges, and, 2 tongs.

a Statistics on hard clams used in this table are based on yields of 11 pounds of meat per bushel in Maine; 11.01 pounds in Massachusetts; 16 pounds in Rhode Island, and 10 pounds a Statistics on soft clams used in this table are based on yields of 15 pounds of meat per bushel in Maine and New Hampshire; 13.64 pounds in Massachusetts; 20 pounds in Rhode Island, and 14.94 pounds in Connecticut. Connecticut.

Nore.—Included in the catch of Massachusetts are 15,098,600 pounds of fishery products, valued at \$465,905, which were taken in the southern winter trawl fishery off southern New Jersey, Maryland, Virginia, and North Carolina. These products consisted principally of croakers, flounders, scup, and sea bass.

Statistics on oysters used in this table are based on yields of 6.57 pounds of meat in Massachusetts, 7.31 pounds in Rhode Island; and 8 pounds in Connecticut.

This item is usually an intermediate product, and although included in the total, may also be shown in its final stage of processing in this or another State.

'This item has been included under "Unclassified products."

Includes fresh fillets of halibut and whiting: frozen fillets of bluefish, halibut, and salmon; fresh steaks of cod, haddock, halibut, pollock, salmon, and swordfish; and frozen steaks Includes fresh fillets of flounder and frozen fillets of cusk, rosefish, wolffish, and hake. of cod, halibut, pollock, salmon, swordfish, and wolffish,

Includes salted fillets of hake and sea herring, dry-salted cusk; and salted boneless hake and whole sea herring.

Includes dry-salted cod, pollock, and haddock; green-salted cod, cusk, pollock, and hake; salted boneless cusk and hake; whole and pickled sea herring, and strips and bits of cod.

\* Includes smoked alewives, butterfish, carp, cod fillets, haddock (finnan haddie), lake trout, mackerel, salmon, sea herring (medium-scaled, and hard and soft bloaters), shad, 8 Includes smoked fillets of cod, haddock, and sea herring; and finnan haddie.

10 This item has been included under "Miscellaneous." and whitefish; and smoked and spiced salmon,

11 This item has been included under "Other" canned products.

<sup>12</sup> Includes canned alewife roe, finnan haddie, mackerel, fish chowder, clam cakes, and cat and dog food.
<sup>13</sup> Includes canned groundfish roe, mackerel, finnan haddie, fish chowder, fiskeboller, hard and soft clam chowder, and rat poison bait.

14 Includes halibut, swordfish, tuna, sablefish, "lingcod," and mixed liver oils. 15 Both 1935 and 1936 data are included in these items.

16 Includes fresh-cooked Jobster meat; fresh-shucked sea mussels; herring dry scrap; soft clam, groundfish, miscellaneous fish and waste fish meals; cod-liver oil; marine-shell buttons

Includes fresh-cooked lobster meat, fresh-cooked packaged crab meat, finnan haddie, canned hard clam chowder, oyster-shell poultry feed and lime, and marine-shell novelties. Includes fresh-shucked oysters, cod and rosefish oil, cod liver pressings, groundfish dry scrap, glue, isinglass, and marine-shell buttons and novelties. Includes smoked butterfish, carp, lake trout, mackerel, salmon, whitefish, and paddlefish or spoonbill cat; and marine-shell novelties.

\$25,476,907; and by fishermen \$880,020. Sone of the above products may have been manufactured from products imported from another State or a foreign country, therefore they cannot be correlated directly with the catch within the State. Of the total number of persons engaged in the preparation of fishermen's manufactured products, 3,664 have also been included as fishermen, and 8 of the persons shown on transporting craft have also been included as fishermen. This should be considered when computing the total number of persons Nore. —Unless otherwise indicated the data are for 1935. The total value of manufactured products for the New England States was as follows: By manufacturing establishments,

in the fishery industries exclusive of duplication,

### VESSEL FISHERIES AT PRINCIPAL NEW ENGLAND PORTS

Due to the importance of the ports of Boston and Gloucester, Mass., and Portland, Maine, as landing points for fishery products, detailed monthly statistics are collected for these landings which are published in the following sections.

### ECONOMIC ASPECT

The landings of fishery products at the three principal New England ports (Boston and Gloucester, Mass., and Portland, Maine), by vessels of 5 net tons capacity or more, during 1936, amounted to 414,767,-145 pounds as landed, valued at \$11,143,545. This is an increase of 11 percent in the quantity of the catch as compared with 1935, and an increase of 24 percent in the value of the catch. The landings at Boston accounted for 339,224,764 pounds, valued at \$9,588,115 or 82 percent of the total volume; the landings at Gloucester amounted to 59,413,534 pounds, valued at \$1,171,681, or 14 percent of the total; and the landings at Portland amounted to 16,128,847 pounds, valued at \$383,749, or 4 percent of the total.

Among the landings of fresh fish, haddock far outranked other species in volume landed. Landings of all sizes in 1936 amounted

to 143,878,750 pounds, or 35 percent of the total fresh fish.

Landings by fishing vessels at the three principal New England ports, 1936

NOTE.—The weights of fresh and salted fish given in these statistics represent the fish as landed from the vessels, and the values are those received by the fishermen. Large cod are classified as those weighing over 10 pounds; market cod, 2½ to 10 pounds, and scrod cod, 1 to 2½ pounds. Large haddock are those weighing over 5½ pounds and scrod haddock, to 10 to 2½ pounds. Large hake are those weighing over 6 pounds and small hake, under 6 pounds. Only landings by vessels having a capacity of 5 net tons or greater are used in this this

### BIOLOGICAL ASPECT

In 1936 the fishing fleet landing fares at Boston and Gloucester, Mass., and Portland, Maine, and operating on the fishing banks of the North Atlantic, numbered 392 steam, motor, and sail vessels of 5 net tons capacity or greater as measured by the United States Customs Service. These vessels were absent from port 55,309 days. The catch of edible fish landed at the three ports amounted to 416,384,118 pounds when the salted fish had been converted to the basis of fresh gutted or round fish as usually landed. This, however, does not represent the entire catch of edible fish of these vessels, for landings were also made at ports in New England other than these three, at New York City, and at more southern ports in connection with the southern winter trawl and mackerel fisheries.

Otter trawls on all sizes of vessels accounted for 309,551,194 pounds, or 74 percent of the total landings. Line trawls were next in importance, accounting for 49,714,305 pounds, or 12 percent of the total

landings.

The catch taken off New England and landed at the three ports amounted to 264,212,798 pounds, or 64 percent of the total; that off Nova Scotia 146,939,445 pounds, or 35 percent; off the east coast of Newfoundland 4,086,552 pounds, or 1 percent; and that off the Middle Atlantic States 1,145,323 pounds, or less than one-half of 1 percent.

<sup>1</sup> Exclusive of duplication.

weight of salted is a new neground ports are boston and Gloucester, Mass., and Portland, Maine. Otter trawls are classified according to the size of the vessel. The "Occasional" after the name of a bank or ground indicates that the vessels or vessels baving a capacity of 5 net tons or greater are used in this tabulation number of vessels fishing, number of reps, and number of vessels fishing, number of reps, and number of days absent, are shown under the principal type of gear used. A trip is shown for each area in which a vessel operated on each voyage. Consequently several trips may be shown for a single voyage.

### MACKEREL FISHERY OF THE ATLANTIC COAST 5

In 1936, the mackerel fleet landed 40,221,600 pounds of mackerel, a decrease of 24 percent as compared with corresponding statistics of the preceding year.

An unusual feature of this year's activity was the fishery in the Block Island region, which extended from May 6 to November 25

and yielded more poundage than the Gulf of Maine.

Of the total landings, about 3,000,000 pounds were tinkers (fish under one pound) and 37,000,000 pounds were of larger sizes. The tinkers were caught between July 1 and October 31, with 91 percent of them being taken during August and September.

Note.—The roman numerals appearing in the box heads of the above table refer to the numbers given these areas by the North American Council on Fishery Investigations.

<sup>&</sup>lt;sup>5</sup> This section, prepared by J. R. Webster under the direction of O. E. Sette of the Division of Scientific Inquiry, includes landings at Portsmouth, Va.; Cape May and Wildwood, N. J.; New York, N. Y.; Newport, R. 1.; New Bedford, Buzards Bay, Provincetown, Boston, and Gloucester, Mass.; and Portland, Maine, by purse-seine vessels "seiners," drift-gill-net vessels "netters," and such boats as fish by the same methods and on the same grounds as the vessels. It does not include the catch of the smaller boats or the catch by other forms of gear.

### FISHERIES OF THE MIDDLE ATLANTIC STATES

(Area XXIII) 6

The most recent complete fishery statistics for the Middle Atlantic States (New York, New Jersey, Pennsylvania, and Delaware) are those collected for the year 1935. In that year the yield of the commercial fisheries amounted to 279,438,100 pounds, valued at \$6,415,664 to the fishermen, representing an increase of 65 percent in volume and 33 percent in value as compared with the catch in 1933, the most recent previous year for which catch statistics are available. Detailed statistics of these fisheries for 1935 appear in "Fishery Industries of the United States, 1936," appendix I to the Report of the United States Commissioner of Fisheries, 1937. A summary of these fisheries and statistics on the catch and operating units of the fisheries of Delaware for 1936 as well as the 1936 shad fishery of the Hudson River appear in the following tables. Data on the fisheries of Delaware for 1936 were made possible through the cooperation of the State of Delaware in furnishing personnel to aid in a survey of that State.

Fisheries of the Middle Atlantic States, 1935

<sup>&</sup>lt;sup>6</sup> This is the number given to this area by the North American Council on Fishery Investigations. It should be explained that there are included in this area craft whose principal fishing ports are in the area but at times fish elsewhere. A notable example is the southern trawl fishery which extends into area XXIV. For a clearer understanding of the statistics published in this section, the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

Excluding the seed oyster fishery. The seed oyster fishery in New York, New Jersey, and Delaware was prosecuted by 1,379 fishermen who used 114 vessels, 73 motorboats, that other boas, 220 detectes, 202 tongs, and 25 nexes, and took 957,370 usbles to seed oysters, valued at \$80,456 from public beds, while 41,574 bushels, valued at \$85,540, were taken from private beds. Of the total number of persons fishing for seed oysters, 1,200 are duplicated among those fishing for market oysters or other species. Similarly, the following card and gear are duplicated: 81 vessels, 33 motorboats, 19 other boats, 164 dredges, 34 tongs, and 8 rakes. Takes.

Statistics on hard clams are based on yields of 16 pounds of meats to the bushel in New York, and 20 pounds in New Jersey, and 10 pounds in Delaware. Statistics on soft clams are based on yields of floorands of meats to the bushel in New York, and 20 pounds in New Jersey.

1 The production of this item is included under "Unclassified products."

2 Data are for 1936.

This item has been included under "Miscellaneous."

Includes smoked butterfish, chubs, haddock fillets, finnan haddie, sea herring (bloaters and kippers)

lake trout, mackerel, salmon, shad, sturgeon, and whitefish; and kippered salmon and shad.

5 Includes canned pickled eels, fish paste, hard-clam products, pickled sea mussels, and terrapin, and

turtle products.
6 Both 1935 and 1936 data are included in these items.

7 Includes fresh fillets of bluefish and halibut; smoked eels; halibut- and tuna-liver oil; menhaden products;

miscellaneous fish meal; and mussel-shell buttons.

8 Includes fresh fillets of cod, flounders and haddock; smoked bluefish, cod, cod fillets and steaks, eels, flounders, goosefish, haddock, lake trout, shad, and sea herring (bloaters); fresh-shucked soft clams; salted boneless cod; canned hard-clam products and oysters; swordfish, tuna and totuava liver oil; and menhaden products.

Includes fresh-shucked hard clams, marine-shell buttons; and miscellaneous fish scrap

10 Includes oyster-shell products, king crab scrap, and menhaden products.

-Unless otherwise indicated, data are for 1935. The total value of the manufactured products for Note.—Unless otherwise indicated, data are for 1935. The total value of the minimatured products for the Middle Atlantic States was as follows: By manufacturing establishments, \$14,691,923; and by fishermen \$378,741. Some of the above products may have been manufactured from fishery products imported from another State or a foreign country; therefore, they cannot be correlated directly with the catch within the State. Of the total number of persons engaged on transporting craft, 125 have been included as fishermen, and among the total number of persons engaged in the preparation of fishermen's prepared products, 552 have been included as fishermen. The whale products shown above were manufactured on a floating factory ship operating in the Southern Hemisphere.

#### VESSEL FISHERIES AT NEW YORK CITY

During 1936 fishing vessels of 5 net tons capacity or greater landed 37,807,000 pounds of fishery products at New York City. The landings consisted of bluefish, 1,228,000 pounds; butterfish, 966,000 pounds; cod, 6,736,000 pounds; croaker, 5,000 pounds; conger eels, 5,000 pounds; flounders, 10,892,000 pounds; haddock, 9,758,000 pounds; hake, 73,000 pounds; halibut, 9,000 pounds; mackerel, 3,434,000 pounds; pollock, 65,000 pounds; sea bass, 594,000 pounds; scup or porgy, 1,066,000 pounds; swordfish, 1,000 pounds; tilefish, 2,563,000 pounds; whiting 288,000 pounds; wolffish, 3,000 pounds; sea scallops, 110,000 pounds; and squid, 11,000 pounds. Data on the landings at New York City are also included in the catch by States.

#### SHAD FISHERY OF THE HUDSON RIVER

The shad fishery of the Hudson River in 1936 was prosecuted by 476 fishermen who used 207 boats, 14 haul seines, 124 drift gill nets, 1,223 stake gill nets, and 16 fyke nets. The total commercial catch amounted to 697,225 shad having a weight of 2,467,900 pounds and a value to the fishermen of \$170,187. This is an increase of 168 percent in the number of shad and 141 percent in their value as compared with 1935. The average price per pound received by the fishermen was about 7 cents compared with a price of about 8 cents in 1935.

Gill nets accounted for 99 percent of the weight of the shad taken, while haul seines accounted for less than 1 percent. Fyke nets

accounted for the remainder of the catch.

Statistics of the catch of shad in the Hudson River also are included in the catch data for New York and New Jersey which are published elsewhere in this report.

#### FISHERIES OF THE CHESAPEAKE BAY STATES

(Area XXIII) 7

The yield of the commercial fisheries of the Chesapeake Bay States (Maryland and Virginia) during 1936 amounted to 314,094,800 pounds valued at \$6,487,641 to the fishermen. This is an increase of 18 percent in volume and 17 percent in value as compared with the catch in the previous year. These fisheries gave employment to 18,283 fishermen or 4 percent less than during 1935.

There were 585 wholesale and manufacturing establishments in the two States in 1936, the same number as in the previous year. In 1936 these establishments gave employment to 12,663 persons, paid \$3,073,443 in salaries and wages, and produced manufactured products (canned, cured, packaged, and byproducts), valued at \$9,813,684. In 1935 the wholesale and manufacturing firms employed 13,213 persons, paid \$3,055,029 in salaries and wages, and produced manufactured products valued at \$9,411,465.

<sup>7</sup> This is the number given to this area by the North American Council on Fishery Investigations. It should be explained that there may be included under this area, craft whose principal fishing ports are in the area but at times fish elsewhere. Data on the operating units and catch of the fisheries of the Chesapeake Bay States have been taken largely from statistics collected by the State fishery agencies of Maryland and Virginia. Supplementary surveys, compilations, and analyses have been made by agents of this Bureau in order that the figures may be presented in a manner comparable with those of other sections. It should be observed that the persons engaged, gear and craft employed, and catch of the seed oyster fishery are not included among the statistics of the fishery for market oysters and other species but are shown in separate tables in this section. For a clearer understanding of the statistics published in this section, the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

<sup>1</sup> Statistics on hard clams used in this table are based on yields of 8 pounds of meats per bushel in Maryland, and 8.02 pounds in Virginia.

2 Statistics on market oysters used in this table are based on yields of 6.15 pounds of meats per bushel in Maryland, and 5.42 pounds in Virginia.

Note.—The seed oyster fishery was prosecuted in this section only in Virginia where 1,397 fishermen using 16 motor vessels, 488 motor boats, 267 other boats, 1,029 tongs, and 188 rakes took 830,094 bushels of seed oysters valued at \$200,724 from public beds and 15,040 bushels valued at \$3,008, from private beds. Of the total number of persons fishing for seed oysters, 1,343 are duplicated among those fishing for market oysters or other species. Similarly, the following craft and gear are duplicated: 10 vessels, 480 motor boats, 248 other boats, 981 tongs, and 188 rakes.

<sup>1</sup> The production of this item is included under "Unclassified products."

<sup>2</sup> This item is usually an intermediate product and, although included in the total, may be shown in its final stage of processing in this or another State.

<sup>3</sup> Includes fresh fillets of haddock, sea robin, scup, and Spanish mackerel. <sup>4</sup> Includes salted spot and corned and tight-pack cut alewives; smoked alewives, butterfish, carp, chub, cisco, tullibees, eels, sea herring, salmon, sturgeon, lake trout, and whitefish.

<sup>5</sup> The production of this item is included under "Miscellaneous."

6 Includes canned fish paste, oysters, and oyster, shrimp, and terrapin soup.
7 Includes alewife and blue crab scrap.

8 Includes miscellaneous fish scrap

9 Includes alewife oil, marine-shell products, and pearl essence.
10 Includes fresh-shucked hard clams, tight-pack alewife roe, menhaden meal, miscellaneous acid scrap. miscellaneous oil, and canned blue crabs.

NOTE.—The total value of manufactured products in the Chesapeake Bay States was as follows: By manufacturing establishments, \$9,813,684; and by fishermen, \$8,325. Some of the above products may have been imported from another State or a foreign country; therefore, they cannot be correlated directly with the catch within the State. Of the total number of persons engaged on transporting vessels 685 have been included as fishermen, and among the total number of persons engaged in the preparation of fishermen's prepared products, all have been included as fishermen.

Note.—Of the total number of persons fishing for seed oysters, 1,343 are duplicated among those fishing for market oysters or other species. Similarly, the following craft and gear are duplicated: 10 vessels, 480 motor boats, 248 other boats, 981 tongs, and 188 rakes.

#### SHAD AND ALEWIFE FISHERIES OF THE POTOMAC RIVER

The catch of shad in the Potomac River in 1936 amounted to 134,409 in number, 359,800 pounds in weight and their total value to the fishermen was \$35,358. The catch of alewives for the same season amounted to 11,287,000 in number, with a total weight of 4,514,800 pounds, and a value to the fishermen of \$36,674. These figures show a decrease of 43 percent in the weight and 37 percent in the value of shad as compared with 1935, and an increase of 1 percent in weight and 38 percent in the value of alewives.

Approximately 68 percent of the shad, in weight, were taken with pound nets, and 30 percent with gill nets. About 99 percent of

the alewives were taken with pound nets, the remainder being taken

with gill nets and fyke nets.

Statistics of the catch of shad and alewives in the Potomac River are also included in the catch data for Maryland and Virginia which are published elsewhere in this report.

#### TRADE IN FISHERY PRODUCTS IN WASHINGTON, D. C.

The municipal fish wharf and market in Washington, D. C., is located in the southwestern part of the city on an arm of the Potomac River. At the present time 18 firms have stalls in this market, 2 are located in the immediate vicinity of the market, 3 have stalls in the Center Market, located at Fifth and K Streets NW., and 2 are located in other parts of the city. Altogether there are 25 firms which employ 131 persons who received \$145,621 in salaries and wages during 1936. Of the total employees 90 were regularly employed. These firms conduct mainly a wholesale business although some retail trade is carried on.

The facilities for handling fish and oysters from boats and vessels that may land at the wharf are good, but only a comparatively small quantity are brought into the city by this method. In the fall and winter, considerable quantities of shell oysters are landed, but most of the oysters handled in Washington are brought in already shucked from Maryland and Virginia, by trucks and other transportation facilities.

During the year 1936 the receipts of fresh and frozen fishery products as received at the municipal fish wharf amounted to 9,395,945 pounds. This is a decrease of 23 percent as compared with 1935, and a decrease of 10 percent as compared with the 5-year average.

During 1936 two firms in Washington, D. C., smoked fishery products and one firm produced shucked oysters. The total value of the products produced by these firms amounted to \$22,424.

Fishery products received at municipal fish wharf and market, Washington, D. C., 1936 1

### FISHERIES OF THE SOUTH ATLANTIC AND GULF STATES

(South Atlantic, Area XXIV; Gulf, Area XXV)<sup>8</sup>

The yield of the commercial fisheries of the marine areas of the South Atlantic and Gulf States (North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas) during 1936 amounted to 556,992,700 pounds, valued at \$13,542,301 to the fishermen, representing an increase of 24 percent in volume and 36 percent in value as compared with the catch in 1934, the most recent year for which catch statistics are available. These fisheries gave employment to 29,006 fishermen as compared with 24,898 in 1934.

There were 703 fishery wholesale and manufacturing establishments in these States in 1936, as compared with 591 in 1934, when the most recent previous survey of these establishments was made. In 1936 these establishments employed 17,095 persons, paid \$3,296,241 in salaries and wages and produced manufactured products (canned, cured, packaged, and byproducts), valued at \$11,445,674. In 1934, the wholesale and manufacturing firms employed 14,354 persons, paid \$2,873,812 in salaries and wages and produced manufactured products valued at \$9,906,595.

<sup>&</sup>lt;sup>1</sup> Statistics on hard crabs used in this table are based on yields of 6 pounds per dozen in North Carolina, South Carolina, and Georgia; 5.96 pounds in Florida; 5.81 pounds in Alabama; 5.50 pounds in Mississippi; 5.59 pounds in Louisiana; and 5.21 pounds in Texas.

<sup>2</sup> Statistics on hard clams used in this table are based on yields of 8 pounds of meats per bushel in all States.

<sup>3</sup> Statistics on market oysters used in this table are based on yields of 4.96 pounds of meats per bushel in North Carolina; 4.64, in South Carolina; 6.01, in Georgia; 4.18, in Florida; 4.11, in Alabama; 3.59, in Mississippi; 3.77, in Louisiana; and 4.92, in Texas.

Note.—The catch for Mississippi includes the following products taken by Mississippi craft in Louisiana waters: Shrimp, 15,748,300 pounds, valued at \$423,899; oysters, market, spring, 4,009,200 pounds of meats, valued at \$244,879; oysters, market, fall, 56,700 pounds, valued at \$3,884. The seed oyster fishery was prosecuted in this section only in North Carolina where 55 regular and 45 casual fishermen using 37 motor boats and 37 dredges took 55,500 bushels of seed oysters, valued at \$11,100, from public beds. Of these regular fishermen 38 are duplicated among those fishing for market oysters or other species. Similarly 14 motor boats are duplicated. boats are duplicated

1 This item has been included under "Unclassified products."

This item has been included under "Miscellaneous." Instead has been included under Miscenareous.

Includes fresh fillets of amberjack, black and red drum, jewfish, king mackerel, mullet, mangrove and red snapper, snook, Spanish mackerel, gray squeteague, and tripletail; and fresh steaks of cabio, red snapper, and snook.

Includes salted bluefish, blue runner, tenpounder, and Spanish mackerel fillets. Includes canned hard-clam products, coquina clam broth, oysters, turtle products, and frog products.
 Includes fresh fillets of bluefish, croaker, red drum, flounders, king whiting, sea bass, Spanish mackerel, spot, and gray squeteague; smoked red drum and mullet; cooked and peeled shrimp; fresh-shucked hard

clams; and oyster-shell lime

Includes packaged fresh-cooked crab meat, and oyster-shell poultry feed and lime.
 Includes pickled shrimp; canned oysters and terrapin products; and menhaden acid scrap and oil.
 Includes menhaden meal; shark skins, fins and oil; packaged fresh-cooked sea crawfish meat; oyster-shell poultry feed and lime; and marine-shell novelties.

10 Includes fresh fillets of Spanish mackerel; fresh steaks of sea bass, and red snapper; frozen fillets of gray squeteague; salted mullet; canned shrimp; and oyster-shell poultry feed and lime.

11 Includes salted mullet, canned crab and shrimp gumbo, and canned shrimp soup.

12 Includes canned fish bouillon, fresh-water crawfish, terrapin meat, turtle soup, and frog products;

and oyster-shell poultry feed and lime.

13 Includes packaged fresh-cooked crab meat and oyster-shell poultry feed and lime.

Note.—The total value of manufactured products in the South Atlantic and Gulf States was as follows: By manufacturing establishments, \$11,445,674; and by fishermen, \$143,784. Some of the above products may have been manufactured from products imported from another State or a foreign country; therefore, they cannot be correlated directly with the catch within the State. Of the total number of persons engaged in preparation of fishermen's manufactured products, 1,132 have also been included as fishermen and 415 of the persons shown on transporting craft have also been included as fishermen. This should be considered when constructed the state of uncluded as fishermen and 415 of the persons shown on transporting craft have also been included as fishermen. sidered when computing the total number of persons in the fishery industries exclusive of duplication.

### SPONGES SOLD AT THE EXCHANGE, TARPON SPRINGS, FLA.

During 1936 sponges sold on the exchange at Tarpon Springs, Fla., amounted to 418,839 pounds, valued at \$1,035,429. This is an increase of 8 percent in quantity and 67 percent in value as compared with the transactions during 1935. Of the total sponges sold on the exchange during 1936, 92,816 pounds, valued at \$371,994, were large wool; 26,572 pounds, valued at \$67,156, were medium and small wool; 197,152 pounds, valued at \$498,604, were wool rags; 76,470 pounds, valued at \$73,839, were yellow; 17,423 pounds, valued at \$17,254, were grass; and 8,406 pounds, valued at \$6,582, were wire. It is estimated that sponges valued at \$4,000 were sold outside of the exchange.

# FISHERIES OF THE PACIFIC COAST STATES 9

The yield of the commercial fisheries of the Pacific Coast States (Washington, Oregon, and California) during 1936 amounted to 1,925,342,300 pounds, valued at \$24,881,509 to the fishermen, representing an increase of 15 percent in volume and 8 percent in value as compared with the catch in the previous year. These fisheries gave employment to 20,620 fishermen as compared with 20,583 in 1935.

O Data on the operating units and catch of the fisheries of the Pacific Coast States have been taken largely from statistics collected by the various State agencies. Supplementary surveys, compilations, and analyses have been made by agents of this Bureau in order that the figures may be presented in a manner comparable with those of other sections. While statistics of the fisheries of California are for the calendar year, those for Oregon and Washington are for the fiscal year ending March 31, 1937, except that statistics of the ballout fishery in these latter States are for the calendar year. For a clearer understanding of the statistics published in this section the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

There were 339 fishery wholesale and manufacturing establishments in the three States in 1936 as compared with 337 in 1935. During 1936 these establishments employed 16,589 persons, paid \$9,365,375 in salaries and wages, and produced manufactured products (canned, cured, packaged, and byproducts) valued at \$52,498,170. In 1935 the wholesale and manufacturing firms employed 14,750 persons, paid \$6,531,351 in salaries and wages, and produced manufactured products valued at \$51,243,348.

<sup>1</sup> The production of this item has been included under "Unclassified products."

<sup>2</sup> This item is usually an intermediate product, and although included in the total, may be shown in its final stage of processing in this or another State.

3 Includes fresh fillets of cod, "lingcod," and rockfishes; frozen steaks of cod and salmon; and fresh-

shucked oysters and bay scallops.

This item has been included with "Miscellaneous."

Includes green salted cod in process, partly boned; spiced and pickled herring; salmon bellies; and stur-

6 Includes salted sablefish, and salmon, and sturgeon eggs for caviar.
7 Includes salted barracuda, black sea bass, cabrilla, pilchards, tuna, and yellowtail; pickled and spiced herring; boneless and absolutely boneless salted cod; green salted cod in process, partly boned; and mild-cured shad. Includes smoked salmon, shad, smelt, and kippered sturgeon.

 Includes smoked chub, mackerel, sablefish, swordfish, and tuna.
 Includes canned salted cod, shad roe, hard clam chowder, and hard clams steamed in the shell.
 Includes canned smoked salmon, salmon eggs for bait, kippered sturgeon, whole razor clams, and razor clam juice.

<sup>12</sup> Includes pilchard, salmon, and salmon-egg meal.
 <sup>13</sup> Includes abalone and miscellaneous fish meal.

14 Includes pilchard and salmon oils, and miscellaneous liver oils.

14 Includes whale, sperm, and miscellaneous fish and liver oils.
15 Includes whale, sperm, and miscellaneous fish and liver oils.
16 Includes smoked herring bloaters and kelp products.
17 Includes fresh fillets of flounders, "lingcod," and rockfishes; fresh-shucked hard clams; salmon and salmon-egg meal; salmon oil; crushed oyster shells for poultry feed and lime; and marine-shell novelties.
16 Includes fresh-shucked eastern, Japanese, and native oysters, canned shad roe, dried shrimp, liquid glue, kelp products, oyster-shell lime, and marine-shell novelties.

Note.—The total value of manufactured products in the Pacific Coast States was as follows: By manufacturing establishments, \$52,498,170; and by fishermen, \$232,099. Some of the above products may have been imported from another State or foreign country; therefore, they cannot be correlated directly with the catch within the State. All of the have been included as fishermen. All of the persons engaged in the preparation of fishermen's manufactured products

! Fished only on Indian reservations.
! In addition, the vessels of the Pacific coast halibut fleet landed approximately 655,000 pounds of halibut, sablefish, and "lingood" livers at Seattle, valued at \$295,000.
! These cod were taken off Alaska.
! Statistics on the catch of salmon except those taken by troll lines, are reported to the State in number rather than pounds. The factors used in the above table for converting number of salmon to weight in pounds were as follows: Blueback, red, or sockeye, 7 pounds; chinook or king, 22 pounds; chum or kets, 11 pounds; humpback or pink, 5 pounds; and silver or coho, 8 pounds.
! The weight of crabs shown is based on an average of 20 pounds per dozen.
! Statistics on hard clams are based on yields of 28 percent edible meats for butter clams and 24 percent for little neck clams.

little neck clams.

7 Statistics on oysters shown are based on yields of 18 percent edible meats for native oysters and 10 percent for Japanese oysters

The weight of bay scallops is based on a yield of 17 percent edible meat.

<sup>&</sup>lt;sup>1</sup> In addition a combined fleet of 16 Puget Sound and California purse seine vessels operated in the Washington coast pilchard fishery. These vessels were manned by a total of 163 fishermen and had an aggregate capacity of 654 net tons. Of the total vessels 15 were from Puget Sound and 1 from California. For detailed statistics regarding the operating units in this fishery refer to the gear tables in the Puget Sound and California sections of this report.

<sup>1</sup> The salmon were caught by Indians fishing on their reservations.
2 Fished by Indians on their reservations.
3 Statistics on the the catch of salmon except those taken by troll lines are reported to the State in number rather than pounds. The factors used in the above table for converting number of salmon to weight in pounds were as follows: Blueback, red, or sockeye, 4.75 pounds; chinook or king, 20 pounds; chum or keta, 11 pounds; ilver or coho, 10 pounds; and steelhead trout, 10 pounds.
4 Steelhead trout shown in this table were taken on Indian reservations.
5 The weight of crabs shown is based on an average of 22 pounds per dozen.

<sup>6</sup> The weight of razor clams shown is in pounds of edible meats, based on a yield of 42 percent of the round

weight.

The statistics on oysters used in this table are based on a yield of 14 percent of edible meats for any 12 percent for Japanese and native oysters, and 13 percent for eastern oysters.

<sup>&</sup>lt;sup>1</sup> In addition a combined fleet of 59 Oregon, Washington, and California purse seine vessels operated in the Oregon coast pilchard fishery. These vessels were manned by a total of 612 fishermen and had an aggregate capacity of 3,226 net tons. Of the total vessels, I was from the Columbia River district of Oregon, 23 from Washington, and 35 were from California. For detailed statistics regarding the operating units in this fishery refer to the gear tables in the Oregon Columbia River, Washington and California sections of this report.

#### HALIBUT FISHERY OF THE PACIFIC COAST 10

The halibut fishery of the Pacific coast, which is prosecuted by United States (including Alaska) and Canadian vessels, ranks as one of the foremost fisheries of that section. During 1936 the total catch of halibut by vessels of both nationalities amounted to 48,054,000 pounds, valued at \$3,603,000. This is an increase of 5 percent in volume and 11 percent in value as compared with the catch and its value in 1935. Of the total catch in 1936, 78 percent was taken by United States craft and 22 percent by Canadian craft. Considered according to ports of landing, 47 percent was landed at Seattle, Wash.; 35 percent at Canadian ports; and 18 percent at ports in Alaska.

<sup>&</sup>lt;sup>10</sup> These statistics are compiled from data collected by the International Fisheries Commission for Washington and British Columbia, and by Bureau agents for Alaska. The weights of the above species represent the fish after evisceration and removal of heads.

<sup>1</sup> Less than \$500.

Note.—In addition to the above it is estimated that about 1,212,000 pounds of halibut, sablefish, "lingcod," and rockfish livers, valued at approximately \$545,000 were landed by the combined fleets at Pacific coast ports during 1936.

The tabulation does not include landings at ports south of Seattle, Wash., which are normally less than 4 percent of the annual Pacific coast catch.

#### VESSEL FISHERIES AT SEATTLE, WASH.

A total of 49,831,417 pounds of fishery products, valued at \$3,254,514, were handled by Seattle wholesale dealers during 1936, exclusive of quantities received by transporting vessels or by rail from Alaska or Canada. This represents an increase of 3 percent in volume and 8 percent in value as compared with the volume and value of the products handled during the preceding year. Of the total quantity 27,059,529 pounds, valued at \$2,201,774, were landed by fishing vessels—an increase of 8 percent in volume and 18 percent in value as compared with the previous year. Receipts by wholesale dealers from sources other than Alaska or Canada or from vessels in the halibut fleet, amounted to 22,771,888 pounds, valued at \$1,052,740, which is a decrease of 2 percent in volume and 8 percent in value.

Fishery products landed by United States vessels at Seattle, Wash., 1936 1

Halibut fleet.
The halibut landed during January were caught prior to the close of the halibut season on Dec. 28, 1935, and were a part of the 1935 quota.

Nore.—The statistics in this table are compiled from reports collected by the Bureau of Fisheries and the International Fisheries Commission.

<sup>1</sup> 47,659 dozen.

#### LAKE FISHERIES 11

In 1936 the yield of the fisheries of the Great Lakes, including those of the international lakes of northern Minnesota, in the United States and Canada amounted to 124,408,100 pounds, representing an increase of 2 percent as compared with the catch in the preceding

vear.

Considering the fishery of United States craft only, the catch amounted to 94,276,500 pounds, valued at \$6,389,443, which is an increase of 4 percent in volume and 7 percent in value as compared with the catch in the previous year. These fisheries gave employment to 5,623 fishermen or 26 percent less than in 1934, the most recent previous year for which statistics on employment are available. During the survey for 1936 data, statistics of the catch in 1935 also were collected. These are presented following the data for 1936.

Lake fisheries of the United States and Canada, 1936

<sup>1</sup> Where there has been a Canadian catch of these species it is included under "Miscellaneous."

<sup>&</sup>lt;sup>11</sup> The statistics of the catch presented herewith were obtained principally from records of the various State fishery agencies. The data for the operating units (fishermen, vessels, boats, and gear) of the United States were obtained largely by Bureau agents in a special canvass; although State records in several instances were very helpful in this work. In all cases the statistics collected are for the calendar year, except for Lake of the Woods, Rainy Lake, and Lake Namakan in Minnesota, which are for two seasons. For Lake of the Woods, the seasons are from June 1 to November 1 and December 1 to April 1 and for Rainy and Namakan Lakes from May 15 to November 1 and December 1 to April 1. The catches for these two seasons, in the order named, have been combined to constitute a year. The quantity of fish taken in these lakes between January 1 and April 1 is estimated at less than 3 percent of the total catch.

1 This item has been included under "Unclassified products."

2 A small amount of smoked chubs, lake trout, and whitefish produced in Indiana is included with the production for Illinois.

Includes fresh fillets of haddock, halibut, and lake trout; and frozen fillets of pike.

Includes fresh fillets of white bass and whitefish; and frozen fillets of pike and yellow perch. The production of this item has been included under "Miscellaneous."

6 Includes fresh fillets of catfish and bullheads, lake herring, mackerel, salmon, suckers, tullibees, and white bass

Includes smoked chubs, eels, goldeye, lake herring, salmon, sturgeon, tullibees, and whitefish.

<sup>8</sup> Includes smoked buffalofish, carp, goldeye, lake herring, shad, and whitefish.

water mussel-shell poultry feed and lime.

 Includes smoked carp, sablefish, salmon, and tullibees.
 Includes smoked cisco, lake herring, sea herring, lake trout, salmon, tullibees, and whitefish, and kippered salmon.

11 Includes fresh fillets of lake herring and whitefish; and smoked lake trout, sablefish, sturgeon, tullibees, and whitefish.

Includes fresh fillets of lake herring and yellow perch; frozen fillets of lake herring; smoked butterfish, carp, mackerel, sablefish, and tullibees; and kippered salmon.
 Includes fresh fillets of lake trout, salted chubs, canned whitefish caviar, burbot liver oil, and fresh-

14 Includes salted lake herring, burbot-liver oil, and burbot and tullibee meal.

-The total value of the manufactured products for the Lake States was as follows: By manufacturing establishments, \$2,660,163; and by fishermen, \$51,438. Some of the above products may have been manufactured from products imported from another State or a foreign country; therefore, they cannot be correlated directly with the catch within the State. All of the persons engaged in the preparation of fishermen's manufactured products have also been included as fishermen and 20 of the persons shown on transporting craft have also been included as fishermen. This should be considered when computing the total number of the products in the product of the persons of the computing the total number of the products of the products of the product of ber of persons in the fishery industries exclusive of duplication.

# FISHERIES OF THE MISSISSIPPI RIVER AND TRIBUTARIES 12

The most recent complete catch statistics of the fisheries for the States of the Mississippi River and tributaries are those collected for the year 1931. The yield of fishery products in that year amounted to 82,382,523 pounds, valued at \$2,897,357, which was a decrease of 22 percent in quantity and 36 percent in value as compared with the quantity and value of the catch in 1922 when the most recent preceding survey was made. Detailed statistics of the fisheries of the Mississippi River and tributaries for 1931 appear in "Fishery Industries of the United States, 1932" by R. H. Fiedler, appendix III to the Report of the Commissioner of Fisheries for the fiscal year 1933. A summary of these fisheries in 1931, as well as certain data for 1936, appear in the following tables.

<sup>&</sup>lt;sup>12</sup> For a clearer understanding of the statistics published in this section, the reader is referred to the section in the latter part of the document entitled "Statistical survey procedure."

<sup>1</sup> Data are for 1936.

<sup>&</sup>lt;sup>2</sup> Data are for 1931 and 1936. Includes smoked buffalofish and tullibees, and mussel-shell chips and novelties.

<sup>&</sup>lt;sup>3</sup> The production of this item is included under unclassified products.

<sup>4</sup> Includes smoked cels, salmon, and sturgeon.
5 Includes smoked buffalofish, butterfish, carp, lake trout, paddlefish, sablefish, salmon, tullibees, and whitefish.

Note.—Unless otherwise indicated the data are for 1931. The total value of the manufactured products for the States of the Mississippi River and tributaries was as follows: By manufacturing establishments, \$4,002,120; and by fishermen, \$8,751. Some of the products may have been manufactured from fishery products imported from another State or a foreign country; therefore, they cannot be correlated directly with the catch within the State.

# FISHERIES OF ALASKA 13

The commercial catch of fishery products in Alaska during 1936, exclusive of whales, amounted to 923,528,817 pounds, valued at \$13,891,412, which is an increase of 45 percent in quantity and 60 percent in value as compared with the catch in 1935. Of the total catch in 1936, 726,853,292 pounds, valued at \$11,856,541, consisted of salmon; 194,125,352 pounds, valued at \$1,882,603, other fish; and 2,550,173 pounds, value at \$152,268, shellfish. In addition, 385 whales were taken. These fisheries gave employment to 11,722 fishermen, 2,064 persons on transporting craft, and 16,597 persons in fishery wholesale and manufacturing industries—a total of 30,383 persons, which is an increase of 34 percent as compared with the number employed in 1935.

<sup>&</sup>lt;sup>13</sup> Statistics for the fisheries of Alaska are collected and compiled by the Alaska Division of this Bureau. A summary of these statistics appears in this section. For detailed figures the reader is referred to "Alaska Fishery and Fur-Seal Industries in 1936," by Ward T. Bower, appendix II to the Report of Commissioner of Fisheries for the fiscal year 1937.

1 Heretofore it was estimated that the shrinkage between the round weight of halibut and the eviscerated, heads-off weight, on which fishermen were paid, was 10 percent, but upon investigation it has been ascertained that the average shrinkage is 30 percent. The latter rate has been used, therefore, in determining the round weight of the halibut taken during 1936.

Nore.—The output of fresh and frozon halibut includes all fares of the Alaska fleet, some of which were landed at other than Alaska ports. The amount of livers landed by the Alaska fleet was not reported, and the quantity shown heretrin is the extinated amount landed in Alaska. The total landings of halibut in Alaska in 1936, other than livers, amounted to 8,658,774 pounds, valued at \$507,484 (finelding 4,000 pounds, valued at \$507, landed by Canadian vessels).

#### STATISTICAL SURVEY PROCEDURE

In order that those who use the statistical data contained in this and previous reports of the Division of Fishery Industries may be informed as to the source of the figures and methods for their collection, it has been deemed advisable to outline, in considerable detail, the statistical survey procedure followed by the Division. This procedure has been developed over a period of years, and changes in method have been made at times where such changes have appeared to work toward general improvement. While the surveys in the several sections are not made in the same manner, owing to varying facilities and records in different States, an attempt has been made to make the data collected by various methods in the producing areas comparable with respect to the same year as well as over a period of years. Throughout the entire plan it has been the intention to coordinate State and Federal fishery statistical work so that there will be as little duplication of effort as possible. The procedure will be discussed under two main heads—"Sectional surveys" and "Local and special surveys."

#### SECTIONAL SURVEYS

Statistical surveys of the fisheries and fishery industries of the various sections of the United States occupy by far the greatest part of the time of the statistical personnel of the Division. It is in the course of these surveys that the statistical and marketing agents visit the individual fishing localities of the various States to collect statistics of the volume of the catch of fish and its value, employment in fishing, quantity of fishing gear, number and classification of fishing and transporting craft, employment in wholesale and manufacturing establishments, and the volume and value of manufactured fishery products and byproducts. The various phases of these surveys are

discussed in detail in the sections following.

History.—The first comprehensive statistical survey of the fisheries and fishery industries of the United States was made for the year 1880 by George Brown Goode, Assistant Director of the U.S. National Museum, and associates, with the cooperation of the Commissioner of Fisheries and the Superintendent of the Tenth Census. Data for specific fisheries, or restricted sections for years prior to 1880, were also collected in this early survey and recorded in Mr. Goode's reports. The survey for 1880, however, did not include the Mississippi River and tributaries. Periodic general surveys of a limited number of States or limited areas of the United States were made for various of the intervening years between 1880 and 1908 and from 1909 to 1928. In 1908 a survey of the entire United States The next general survey of the entire United States was not made until 1931, although complete data for all sections, excluding the Mississippi River and tributaries, were collected for 1929 and 1930. Complete data on the catch and operating units for all sections, excluding the Mississippi River and its tributaries, were collected for 1932. In the latter survey, however, lack of sufficient funds prohibited collection of data on wholesale and manufacturing firms except those data collected as a part of the canned fishery products and byproducts surveys. Complete general canvasses were made of the Chesapeake and Pacific States for the years from 1933 to 1936, inclusive, the New England and Middle Atlantic States for 1933 and 1935, and the South Atlantic, Gulf, and Lake States for 1934 and 1936. Complete data on the catch of the fisheries of the Lake States were

also collected for 1933 and 1935.

Following is a summary indicating the years for which statistics were collected on the fisheries and fishery industries in the various sections. Figures for the more recent years are available for free distribution from the Bureau in bulletin form, but figures for the earlier years are available only in the various printed reports of the Bureau. These reports are available for reference in the Bureau's

library and at many public libraries.

In the New England States statistics on the catch of the marine fisheries, and those conducted in the coastal rivers and bays of these States, were collected for the years 1880, 1887, 1888, 1889, 1898, 1902, 1905, 1908, 1919, 1924, 1928, 1929, 1930, 1931, 1932, 1933, and 1935. For most of these years data on operating units and wholesale and manufacturing trade also were collected. In addition to the above, a partial statistical survey was made for the entire section in 1892; a partial survey of the fisheries in Maine, New Hampshire, and Massachusetts for the fiscal year 1897; the lobster fishery for 1900 and 1913; the oyster fishery for 1910; the shad and alewife fisheries for 1896; the menhaden industry for 1912; the fisheries of Massachusetts for 1879; and the fisheries of Connecticut for 1925 and 1926.

Statistics on the catch of the marine fisheries and those conducted in the coastal rivers and bays of the Middle Atlantic States were collected for the years 1880, 1887, 1888, 1889, 1890, 1891, 1897, 1898, 1901, 1904, 1908, 1921, 1926, 1929, 1930, 1931, 1932, 1933, and 1935. Data on operating units and wholesale and manufacturing trade also were collected for most of these years. In addition to these a statistical survey was made of the coastal fisheries of these States in 1915; catch in all States except New York, in 1892; the shad and alewife fisheries in 1896; the shad fisheries of the Delaware River in 1910; the shad fisheries of the Chesapeake Bay and tributaries in 1909; the menhaden industry in 1912; the lobster fisheries in 1900 and 1913; and the oyster fishery in 1911. The years for which statistics are available on the shad fishery of the Hudson River are given in the section entitled "Shad and alewife fisheries."

In the Chesapeake Bay States statistics on the catch of the marine fisheries and those conducted in coastal rivers and bays of these States were collected for the years 1880, 1887, 1888, 1890, 1891, 1897, 1901, 1904, 1908, 1920, 1925, and for all the years from 1929 to 1936, inclusive. Data on operating units and wholesale and manufacturing trade also were collected for most of these years. In addition to the above, a statistical survey was made of the crab fishery for 1915; the oyster fishery and menhaden industry for 1912; and the shad and alewife fisheries for 1896, 1909, and 1915. The years for which statistics of the shad and alewife fisheries of the Potomac River are available are given in the section entitled "Shad and alewife fisheries."

In the South Atlantic and Gulf States statistics on the catch of the marine fisheries and those conducted in the coastal rivers and bays of these States were collected for the years 1880, 1888, 1889, 1890, 1897 1902, 1908, 1918, 1923, 1927, 1928, 1929, 1930, 1931, 1932, 1934, and 1936. Data on operating units and wholesale and manufacturing trade also were collected for most of these years. In addition to the above, a

statistical survey was made of the fisheries of these States, excluding Florida and Alabama, for 1887; the shad fishery of the South Atlantic States for 1910; the shad and alewife fisheries of the South Atlantic States for 1896; the sturgeon fishery of Florida for 1900; the menhaden industry of the South Atlantic States for 1912; the shrimp fishery for 1916; the oyster fishery of the South Atlantic States for 1910; and the oyster fishery of the Gulf States for 1911.

In the Pacific Coast States statistics on the catch of the marine fisheries and those conducted in the coastal rivers and bays of these States were collected for the years 1880, 1888, 1892, 1895, 1899, 1904, 1908, 1915, and for all the years from 1922 to 1936, inclusive. These surveys have usually included data on operating units and wholesale and manufacturing trade. In addition to the above, statistics were obtained on the fisheries of California from 1918 to 1921, inclusive, and

for the oyster fishery in 1912.

Statistics on the catch of the fisheries of the Great Lakes were collected for the years 1880, 1885, 1890, 1893, 1899, 1903, 1908, and for all the years from 1913 to 1936, inclusive. Statistics of the operating units and of the wholesale and manufacturing trade were collected for most of the years when canvasses were made from 1880 to 1908, and in 1917 and 1922 as well as in most of the years from 1926 to 1936, inclusive. In addition to the above a survey was made of the fisheries of Lake Ontario and of certain fisheries in other lakes for the year 1897.

Statistics of the catch of the fisheries of the Mississippi River and its tributaries were collected for the years 1894, 1899, 1903, 1908, 1922, and 1931. In addition, figures have been obtained of the fisheries of Lakes Pepin and Keokuk for the years 1914 and 1917 and the years from 1927 to 1936, inclusive, and of the fisheries of the Mississippi River between Lakes Pepin and Keokuk for the years 1929 to 1936, inclusive.

Statistics also were collected on the fisheries of certain interior waters, other than the fisheries of the Great Lakes and the Mississippi River and its tributaries, for the years 1894, 1895, 1900, and 1902. Statistical agents.—The statistics contained in this volume have been

Statistical agents.—The statistics contained in this volume have been collected by a corps of trained statistical and marketing agents which comprises a part of the permanent staff of the Division of Fishery Industries of the Bureau. Most of these men have been with the Bureau for a period of 5 years or more. In the main they are college graduates and were recruited through civil-service examination. While in college, most of the men pursued biological or technical courses, largely in fishery work, which has especially suited them for coping with the many biological and technical aspects encountered in canvassing the fisheries. This training has been especially helpful in identification of the species which, because of the many local names applied to a particular species, causes considerable confusion.

Period covered.—In conducting the fishery statistical surveys, agents are dispatched to the districts to be surveyed as early in the calendar year as they can be spared from the tabulation and preparation for publication of their previous season's work. They collect statistics of fishery operations for the year preceding that in which they are working; and, since their field work occupies the greater part of the year, it is usually at least a year from the end of the calendar year for which they are collecting data until the figures are published. Most of

the figures are collected for the calendar year. Where there are variations from this general practice, explanatory notes appear in the tables. Prior to 1930, statistics on the catch of oysters in the Atlantic and Gulf States were collected for the oyster season; that is, from September to April, inclusive. Beginning with 1930 and down to the present, they

have been collected on the basis of the calendar year.

Scope.—The scope of the coastal statistical surveys includes canvasses of the commercial fisheries of the oceans and bays and of the coastal rivers as far inland as commercial fishing is important. This usually coincides with the range of commercial fishing for anadromous species. Statistics of the fisheries of the Mississippi River cover canvasses of the fisheries of the Mississippi River proper as well as all of its tributaries wherein commercial fishing for either fish, crustaceans, or mollusks is prosecuted. Statistics of the fisheries of the Great Lakes cover canvasses of the fisheries prosecuted in the Lakes proper, adjacent bays, and the international lakes of northern Minnesota, as well as rivers which sustain a commercial fishery having outlets into these waters. Surveys for statistics of the wholesale and manufacturing fishery industries cover such plants located in the coastal, river, and lake areas adjacent to the waters mentioned above.

Methods of collection.—Several methods for the collection of fishery statistics are employed, each of which has been carefully studied to obtain the best results with the available personnel and funds. In most instances the agents obtain lists of the names of fishing vessels, names or numbers of motorboats, and names of owners of these craft from local customs officials. Also it often is possible to obtain the names of licensed commercial fishermen and occasionally some statistics on the catch from several of the State fishery agencies; from other

State, county, or city agencies; or from private organizations.

With such preliminary records as are available for their guidance the agents then visit each fishing community in their field unless their preliminary records are so complete that personal visits in some areas may be eliminated. While it is impossible for the few agents available for this work to interview each fisherman in a given locality, the more important ones are visited, and a sufficient number of those of lesser importance are interviewed to obtain reliable information on their production. In practice virtually all wholesale firms are visited, as well as captains of fishing vessels (those of 5 net tons or over), and also most of the more important inshore fishermen.

In the Great Lakes and Pacific Coast States such exceptional cooperation has been obtained in recent years from the State fishery agencies in the collection of statistics that only fragmentary surveys need be made by the Bureau's agents to obtain the necessary data. Also the State fishery agencies in Delaware, Maryland, and Virginia recently have developed very complete statistical systems which

greatly facilitate the Bureau's canvasses in these States.

As regards the fisheries of the Great Lakes and international lakes of northern Minnesota the Bureau obtains most of the catch statistics and usually the value of the catch direct from the records of the State fishery agency. To obtain data on the number of fishermen, boats, vessels, and gear the Bureau conducts such personal surveys among the fishermen as may be necessary to supplement the State records.

Bureau agents are stationed at Seattle, Wash., and Terminal Island, Calif., who survey the fisheries of the Pacific Coast States. As a rule they obtain figures on the volume of the catch from the records of the several State fishery agencies. In most cases the value of the catch is derived from dealers' records and sometimes from estimates of prices. In Washington and Oregon the offshore fisheries are surveyed separately by the Bureau's agent to obtain data on the number of operating units, catch, and value of the catch. Statistics of the wholesale fishery industry for this section are obtained largely by personal interviews of the agents.

In the administration of the Alaska fisheries the Bureau obtains sworn statements concerning their activities from those prosecuting the fisheries in this area. These statements are compiled by the

Alaska Division of this Bureau.

Statistics of the volume of the catch of fish of the Pacific Coast and Great Lakes States are usually shown in weights as landed, which may be in the round or dressed condition. Statistics on the volume of the catch of fish taken in the remainder of the United States are shown in round weight.

The figures in the tables for shellfish represent the weight of the meats in the case of univalve and bivalve mollusks and gastropods, and the round weight of crustaceans and such mollusks as squid and

octopus.

Shore and vessel fisheries.—In general, statistics of the shore fisheries, as collected by the agents, include data on the number of casual and regular fishermen; number of motor and other fishing boats and accessory boats; kind and quantity of gear used, and the volume, value, and method of capture of each species caught by boats (for our purpose craft of less than 5 net tons capacity are called "boats") for each locality or group of localities. This method is not followed in some sections where the availability of data collected by the State fishery agencies obviates the necessity of detailed locality surveys.

Statistics of the vessel fisheries include data on the number of the crew, rig of vessels, net tonnage, kind and quantity of gear used, accessory boats carried, and volume, value, and method of capture of each species caught by each vessel (for our purpose craft of 5 net tons' capacity or more are called "vessels"). As in the shore fisheries, the availability of figures collected by State fishery agencies may eliminate the necessity of our agents collecting these data for each

vessel.

All persons engaged in commercial fishing operations are included as fishermen. For our purpose these have been divided into "regular" and "casual" fishermen. Regular fishermen are those who receive more than one-half of their annual income from fishing; and casual fishermen are those whose principal business is something other than fishing, and who receive less than one-half of their annual compensation from fishing.

The catch of fish is credited to the principal port of arrival and departure of the craft rather than its point of ownership, registration, documentation, or its port of landing. This accounts for catches of fish being shown in areas where they are not common, since fishing vessels frequently fish in areas far from their principal fishing port.

Wholesale and manufacturing trade.—All persons or firms engaged in the wholesale buying and selling of fishery products or who produce manufactured fishery products are surveyed under this title. Where the business of fishing and wholesaling or manufacturing is combined. that part of the business devoted to either of the latter two phases is included in the wholesale and manufacturing survey and the part devoted to fishing is included in the shore or vessel fisheries. wholesale business is conducted with no manufacturing and the business is so small that the full time of one man over the whole year or season is not required, it is then disregarded as a wholesale business. If commodities other than fishery products are handled, the persons engaged, and salaries and wages paid, are prorated; and only that part concerned with fishery products is included. If such a firm required less than the full time of one man over the whole year or season and if it does not manufacture, it is not included in the can-Retail firms that manufacture or whose wholesale business exceeds the retail part are included. Persons or firms engaged in the motortrucking of fishery products are included as wholesalers if they are engaged in wholesale buying and selling.

Buyers for a central firm are not canvassed as wholesale dealers unless they ship direct to the firm's customers from the buying point.

Fishermen or fishing concerns, except manufacturers, who do not buy fishery products are not included under this heading except that oyster-shucking firms are included provided shuckers are employed, and irrespective of whether all or part of the oysters used are taken from the firms' privately owned beds.

Manufacturing concerns include those which prepare packaged fishery products; salted, spiced, smoked, dried, or otherwise cured fishery products; canned fishery products; or fishery byproducts.

fishery products; canned fishery products; or fishery byproducts.

Fishermen who manufacture are surveyed to obtain the number of persons so employed and the volume and value of the products

prepared.

In collecting statistics of manufacturing firms, the agents obtain data on the production for each plant in producing areas of products as marketed by the plant. Such products are usually "final" and in form for consumption; however, the products may be "intermediate" and require further processing before reaching the consumer An outstanding example of an intermediate product is green-salted groundfish which almost invariably is further processed before final marketing. In reviewing the statistics of manufactured products it should be observed that intermediate products are not shown where they are prepared to the final stage in the original plant. An exception to this rule, however, is in the case of the production of mild-cured salmon, which, on account of its importance, is shown in its entirety, whether further processed in the producing plant or not. In this connection it should also be stated that several of the byproducts for which statistics are shown may be intermediate. and the plants producing the final products are not surveyed by this Bureau. Outstanding among such products are marine-animal oils. scrap, and meal.

Statistics of persons engaged in wholesale and manufacturing establishments are reported in three groups: Proprietors, salaried

employees, and wage earners.

Proprietors represent those persons who devote their time to the conduct of the enterprise and receive their compensation in the form of profits. Managers of branch houses are not classified as pro-

prietors.

Salaried employees usually include those persons paid by the week or month, while wage earners usually consist of those paid on a per diem or piece-work basis. This, however, is not true in all cases, since the distinction between these two classes depends primarily on the character of the work done rather than the unit of time employed for calculating rates of pay. In general, office employees are classified as salaried employees. Other employees, including plant workmen, are classed as wage earners. Plant foremen or superintendents are classified as salaried employees unless they are principally engaged in manual labor; in which case they are classified as wage earners. Active officers of corporations are classified as salaried employees. Statistics of wage earners are shown in two forms: The average number employed during the operating season; and the average number employed during the year (the monthly average for the year).

Transporting trade.—Statistics are obtained on the number of the crew and number of boats and vessels engaged in transporting fishery products from the fishing grounds to port or from port to port. However, if a craft is engaged in catching fish at any time of the year it

is included as a fishing craft rather than as a transporter.

Publication of data.—Statistics of employment in the fisheries, craft and gear engaged, catch and value of catch, and certain data on industries related to the fisheries are summarized and published in bulletin form as soon as possible after completion of each survey. Later the figures in more detail are included in the annual reports of the Division.

#### LOCAL AND SPECIAL SURVEYS

Landings at certain important United States ports.—Statistics of the landings of aquatic products at the principal New England ports (Boston and Gloucester, Mass., and Portland, Maine) are obtained in a similar manner. An agent is permanently stationed at Boston, Mass., and another is assigned to the ports of Gloucester, Mass., and Portland, Maine. Their duties include the obtaining of figures daily on the quantity of fish landed by each fishing vessel, the value of such fish landed, information concerning the date of departure and arrival of the vessel, and they also indicate the grounds from which the fish were taken and gear used in their capture. These data are forwarded to the Bureau, where compilations are made. American fisheries received duty free at Boston and Gloucester, Mass., and Portland, Maine, from the treaty coasts of Newfoundland, Magdalen Islands, and Labrador are included in the landings at these ports; however, they are not included in the catch in sectional fishery surveys of the New England States unless they represent a catch by United States vessels. Statistics of these landings are released monthly and annually in bulletin form and detailed data are published in the annual reports of this Division. Data on the landings at Boston, and Gloucester, Mass., have been collected annually since 1893, and those for Portland, Maine, since June 1915. Some data are available for Boston and Gloucester prior to 1893.

Statistics of the landings of fish at Seattle, Wash., are collected by the Bureau's agent in that city. Landings are classified as those

made by United States fishing vessels and those received by Seattle whole ale dealers. The landings credited to United States fishing vessels are made by vessels operating distinctly as primary fishing units, usually in the offshore fisheries, while those credited as received by wholesale dealers are usually products of the shore fisheries collected mainly from points in Puget Sound and do not include fish received from Alaska or Canada, or landings made by the halibut fleet. Statistics of these landings at Seattle are released monthly and annually in bulletin form and detailed data are published in the annual reports of this Division. Statistics of the landings by fishing vessels at Seattle have been collected since June 1915 and certain data on products received by Seattle wholesale dealers since December 1915.

Statistics of the fishery products handled at the municipal wharf, Washington, D. C., are reported to the Bureau by agents of the Health Department in Washington. They are not published in bulletin form, but a summary of the year's activities is published in the annual reports of the Division. Data on products handled at the

municipal wharf are available since 1921.

Atlantic mackerel fishery.—Statistics on the catch by the Atlantic mackerel fleet are obtained by combining the figures of mackerel landed at Boston and Gloucester, Mass., and Portland, Maine, with those obtained by Bureau agents, who in recent years have been stationed at other Atlantic ports where mackerel are landed. These agents obtain data on the volume of mackerel landed in a manner similar to that used to obtain figures on the landings by fishing vessels at the three New England ports. The figures include only the catches made by purse seine and drift gill net craft and are not complete for craft of under 5 net tons' capacity using this type of gear. Statistics of this fishery appear only in the annual reports of this Division, although the landings at the principal New England ports appear in the monthly and annual bulletins published for those ports. Statistics of this fishery are available from 1905 to 1936, inclusive.

Shad and alewife fisheries.—Owing to the importance of the Hudson and Potomac Rivers in the production of shad, surveys for statistics of the catch, value of the catch, and operating units are made annually. On the Potomac River similar statistics also are obtained for the alewife fishery. Much of the data required for these surveys are avail-

able from the State fishery agencies.

Statistics of the shad and alewife fisheries are not published separately in bulletin form, but a summary of the year's activities is

published in the annual reports of the Division.

Statistics of the shad fishery of the Hudson River are available for 1896, 1897, 1898, 1901, 1904, 1910, and from 1915 to 1936, inclusive, while data for the shad fishery of the Potomac River are available for 1896, 1901, 1904, 1909, 1915, and from 1919 to 1936, inclusive. Statistics of the alewife fishery of the Potomac River are available for 1896, 1909, 1915, and from 1919 to 1936, inclusive.

Pacific halibut fishery.—Statistics of the Pacific halibut fishery are obtained by the Bureau's agent in Seattle, aided by Bureau representatives in Alaska and the International Fisheries Commission. The fleet classification has been arbitrarily applied by including in the "Washington fleet" all United States and Alaska vessels that land more than half of their catch in that State. All other United States and Alaska vessels of the halibut fleet are included in the "Alaska

fleet." Monthly and annual statistical bulletins are available on this fishery, being published along with the statistics of the landings of fishery products at Seattle, Wash., and detailed statistics are published in the annual reports of the Division. Statistics of the landings of halibut at Pacific coast ports have been collected since 1925.

Canned fishery products and byproducts.—Beginning in 1921, the Bureau has made annual surveys for statistics of the canned fishery products and byproducts industries of every section. These are begun the first week in January of each year for statistics of the production in the preceding year. The surveys usually occupy 6 to 9 weeks' time. During this period the Bureau obtains by mail, so far as possible, the production of canned fishery products or byproducts from each plant in the United States engaged in this business. Where it is impossible to obtain reports by mail the report is obtained by personal visit by the Bureau's agents. They obtain statistics of the production and value of the production for each commodity. Statistics of the canned fishery products and byproducts produced in Alaska are received on the same statements obtained by the Bureau that include statistics of general fishery operations.

An annual statistical bulletin is issued on this trade, and detailed statistics of the output are published in the annual reports of the Division. In addition to the data obtained on the output of these products annually since 1921, data also usually were obtained prior

to 1921 for the years the various sections were surveyed.

The value shown for canned products constitutes the gross amount received by the packer at the production point, no deductions being

made for commission or expenses.

Packaged-fish trade.—Complete statistics of the annual production and value of fish packaged in the United States are obtained as a part of the survey for the statistics of the canned fishery products and byproducts industries. These statistics are released in bulletin form annually and detailed statistics are published in the annual reports of the Division. Statistics of the production of packaged fish are

available for 1926 and the years from 1928 to 1936, inclusive.

Cold-storage holdings of fish.—An arrangement has been made with the Bureau of Agricultural Economics, Department of Agriculture, whereby statistics of the cold-storage holdings of the various species of fish, by sections of the United States are furnished to this Bureau monthly. Included with statistics of the holdings are statements of the quantity of the various species of fish frozen and also the holdings of certain cured fish. Bulletins showing these statistics are issued monthly as well as annually, and detailed statistics are published in the annual reports of this Division. Statistics of cold-storage holdings of fishery products have been published since 1917 and data on quantities of fish frozen, for the years from 1920 to 1925, inclusive, and from 1928 to 1936, inclusive.

Sponge market, Tarpon Springs.—A large proportion of the total

Sponge market, Tarpon Springs.—A large proportion of the total output of sponges in Florida is handled through the sponge exchange at Tarpon Springs. In view of this, the Bureau has obtained from a representative of the exchange annual statistics of the quantity and value of the sponges, by variety classification, handled through it annually. Statistics of the quantity of sponges handled through the exchange are not published in bulletin form, but a summary of the year's activities is published in the annual reports of this Division.

Statistics of the transactions on the sponge exchange are available for

1913, 1914, and for the years from 1917 to 1936, inclusive.

Foreign fishery trade.—Statistics of the foreign fishery trade are obtained from compilations made by the Bureau of Foreign and Domestic Commerce, Department of Commerce. Statistics of all known fishery products imported or exported have been assembled in one table and published annually in the reports of the Division in recent years. For earlier years they are available in the reports of the Bureau of Foreign and Domestic Commerce, the Bureau of Statistics, the Department of Commerce and Labor, or the Treasury Department.

# PRACTICES AND TERMS

Certain practices and terms of importance used in the compilation

of fishery statistics are explained below.

Days absent.—In computing "days absent" for vessels landing fares at the various ports, the day of departure and the day of arrival are included; thus a vessel leaving port on the 8th of the month and returning on the 15th of the month will be shown as being absent 8 days.

Operating units.—Operating units as referred to in this document include persons engaged in the fisheries, and fishing craft and gear

employed.

Vessel.—The term "vessel" refers to a craft having a capacity of 5 net tons or more.

Boat.—The term "boat" refers to a craft having a capacity of less

than 5 net tons.

Incidental catch.—The term "incidental catch" refers to the catch of certain species by a type of gear which ordinarily does not capture

Percentages.—Percentages are usually shown as whole numbers. Fractions of percents are dropped if less than five-tenths, and the percentage is raised to the next higher integer if the fraction is greater than five-tenths. If the fraction is exactly five-tenths, the integer is

raised or lowered to make it an even number.

Converting.—Many of the figures shown in the statistical tables published herewith have been converted to thousands of pounds or dollars. In making these conversions the largest number from which a group of items is computed is raised or lowered to the nearest thousands place. If the number ends in an even 500, the thousands integer is raised or lowered to make it an even number. The individual items are changed to conform to the total thus obtained.

Confidential data.—The statistical data collected by the Division are confidential and are not released except by approval of the Washington office. Statistics of production of wholesale and manufacturing firms are published only for commodities or geographical areas where the production of three or more concerns may be grouped. Every effort is made to publish only those figures which will not reveal individual enterprise.

CONVERSION FACTORS

It is the policy of the Bureau to show the detailed catch figures of all products in pounds for the sake of uniformity and for purposes of comparison. Following such a policy presents certain problems. In the case of fish there is little difficulty since in very rare instances are such products reported in units of measure other than pounds. For shellfish, however, the units of measure may be bushels, sacks, barrels, or thousands of shellfish, gallons of meats, etc. These many units make standardization difficult, but when coupled with the wide variation in the requirements or definition of some of these units in the various States the problem becomes even more complex.

All bivalve mollusks are reported in pounds of meats in the detailed catch tables presented in this report. In addition, there are included supplementary tables for most of the sections, which give data on the production in bushels. These supplementary tables also give the production of certain other shellfish, such as crabs, in number.

Oysters.—Probably the greatest problem in presentation of fishery statistics in uniform units of measure is in the case of oysters. Usually the production of oysters on the Atlantic and Gulf coasts is reported to Bureau agents in bushels; and prior to the data obtained for the year 1930 conversion from bushels to pounds of meats was effected on the basis of a uniform yield of 7 pounds of meats to the bushel. However, more recent investigations have shown considerable variation from this figure. There follows a table which gives the results of these studies of the measures used for oysters in the various States and of the average yields per bushel. This table presents the factors that have been used in the oyster statistics given in this report.

# Measures and yields of oysters 1

			Market	oysters

# COMMON AND SCIENTIFIC NAMES OF FISHERY PRODUCTS

In order to prevent misunderstanding in the use of common names employed in the tables and discussions, the following list of common and scientific names is given:

Common and scientific names of the commercial fishery products caught in the United States and Alaska

Common name as shown in Bureau reports	Other common names	Scientific names
Albacore	See tuna (Branch herring, wall-eyed or big-eyed herring. (Blueback, glut herring	Pomolobus pseudoharengus.
Alewives	herring.	
Amberjack	(Blueback, glut herring	Pomolobus astivalis. Seriola species. [Engraulis mordax.
Anchovies		Anchoviella delicatissima. Anchoviella compressa.
		Pomacanthus arcuatus.
Barracuda	Smallmouth bass	Sphyraena argentea.
Black bass	Smallmouth bass    Largemouth bass    Toilon	Micropterus dolomieu. Micropterus salmoides.
Bluefish	Tailor	Pomatomos saltatrix.
Blue pikeBlue runner or hardtail	Tailor Pike perch, blue pickerel (Canada) Runner	Stizostedion glaucum. Caranx crusos.
		(Sarda sarda,
		I Saraa chillensis.
Buffalofish		Ictiobus species.
Butterfish		Poronotus triacanthus.
Burbot	Lawver, ling	Lota maculosa.
Cabio	Coalfish, crab eater, cobia Rock bass	Rachycentron canadus.
Cabrilla	Rock bass	Epinephelus analogus (Pacific coast).
Carp	German carp	Cyprinus carpie.
Catfish and bullheads		Ameiurus species. Ictalurus species.
Chubs	Tullibee in Canada; longjaw, bluefin, blackfin in United States.	Leptops olivaris.   All Leuchichthys except artedi (in Great   Lakes).
Cigarfish		Decapterus punctatus.
Cisco.	Herring in Canada	Leucichthys artedi (Lake Erie only).
Cod	_	(Gadus macrocephalus (Pacific coast).
		(Gadus callarias (Atlantic coast).
Crappie	White crappie. Black crappie, strawberry bass, calico bass.	Pomoxis annularis. Pomoxis sparoides.
Crevalle	( 5455.	Caranx hippos.
Croaker	Crocus, hardhead	Micropogon undulatus.

# Common and scientific names of the commercial fishery products caught in the United States and Alaska—Continued

unner	Chogset, blue perch, bergall	Tautogolabrus adspersus.
Cusk		Brosme brosme.
Oolly Varden trout	Salmon trout, bull trout	Salvelinus parkei.
Oolphin		Coryphaena hippurus.
Drum:		De sandas ausuria
Black		Pogonias cromis.
Red	Channel bass, redfish, spotted bass	Sciaenops ocellatus.
Cels:		Amouilla nontrata
Common		Anguilla rostrata.
Conger lounders	Flour dans Sulves soles ((Colifornia	Leptocephalus conger. Pleuronectidae species.
lounders	Flounders, flukes, soles, "California halibut," dabs.	i leuronectidae species.
Twingfah	namout, dabs.	Cypsilurus californicus.
'lyingfish 'rigate mackerel	"Boo Hoo"	Auxis thazard.
Parfish	See sea gar	220000000000000000000000000000000000000
izzard shad	Nanny shad, mud shad	Dorosoma cepedianum.
oldeye		Hiodon species.
oldfish	Sand perch	Carassius auratus.
loosefish	Allmouth	Lophius piscatorius.
	(Dogfish	Squalus sucklii (Pacific coast).
rayfish	!Spiny dog	Squalus acanthias.
	Smooth dog	Mustelus mustelus.
roupers	"Sea bass"	Epinephelus species.
		Myceteroperca species.
runts	Margatefish, sailors choice (Key West)	Haemulon species.
Iaddock		Melanogrammus aeglefinus.
f - 1	Squirrel hake, Boston hake, ling, black	Urophycis species (Atlantic coast).
[ake	hake, mud hake.	Marlanaina mundantus (Danife annat)
F-1214	[Merluccio	Merluccius productus (Pacific coast).
[alibut		Hippoglosuss hippoglossus. Orthodon microlepidotus (Pacific coast)
Iardhead Iarvestfish	Ctonfish dellarfish nonnyfish hytten	Peprilus alepidotus.
larvestusii	Starfish, dollarfish, pappyfish; butter- fish (N. C.).	1 epittus uteptilotus.
Terring:	ush (N. C.).	
Lake	Herring	Leucichthys artedi (Great Lakes, excep
Dake	Henring	Erie).
Round		Etrumeus sadina.
		Clupea harengus (Atlantic coast).
Sea		(Clupea pallasii (Pacific coast).
ferring smelt	Sea smelt	Argentina silus.
lickory shad	Tailor shad, skip	Pomolobus mediocris.
logfish	Capitaine, perro perro	Lachnolaimus maximus (Florida).
forse mackerel	Pacific	Trachurus symmetricus.
	(Atlantic—See tuna.	B
ewfish		Promicrops itaiara.
	King mackerel, cerro	Scomberomorus cavalla (Atlantic coast)
ingfish	[ ]	Scomberomorus regalis (Atlantic coast)
ing whiting	Little roncador, croaker	Genyonemus lineatus (California).
ing whitingake trout	Northern whiting, kingfish, sea mink	Menticirrhus species. Cristivomer namaycush.
amprey		Petromyzon marinus.
amprey	Sand eel, lant, sand launce	Ammodytes americanus.
aunceLingcod"	Cultus cod, blue cod, buffalo cod, ling.	Ophiodon elongatus.
		Scomber scombrus (Atlantic coast).
fackerel		Scomber diego (Pacific coast).
farlin	Spearfish	Tetrapturus mitsukurii (Pacific coast)
Ienhaden	Mossbunker, pogy, fatback	Brevoortia tyrannus.
finnows		Cyprinidae species.
Iojarra		Eucinostomus species.
Iooneye	Toothed herring	Hiodon species.
-		Vomer setipinnis.
Ioonfish		\Selene vomer.
Tullet	Jumping mullet	Mugil species.
fummichog	Mayfish, killifish	Fundulus species.
Iuttonfish		Lutianus analis.
addlefish	Spoonbill cat.	Polyodon spathula.
erch (California)	See surffishes.	
ermit	See pompano.	Outhornistic shows at the
igfish	Hogfish (N. C.)	Orthopristis chrysopterus.
ike or pickerel	Great Lakes pike	Esox reticulatus.
-		Esox lucius.
ilchard	Sardine	Sardina caerulea.
ilotfish		(Naucrates ductor.
1	Bream, salt-water bream	\ Seriola zonata.
infish ollock		Lagodon rhomboides.
UIIUCK	(Parmit great nampana	Pollachius virens.
ompano	Permit, great pompano	Trachinotus goodei.
ошрапо	{	Trachinotus species (Atlantic coast).  Palometa simillima (Pacific coast).
orgies	Porgee	Calamus species.

# Common and scientific names of the commercial fishery products caught in the United States and Alaska—Continued

Common name as shown in Bureau reports	Other common names	Scientific names
Quillback	Spearfish or skimfish	Carpiodes species.
Roach	Shiner	Notemigonus crysoleucas.
Dools hoss	Redeye, goggle-eye	Ambloplites rupestris (Mississippi River
Rock bass	Grannana	to Atlantic seaboard)
Rockfishes Rosefish	[Groupers Rock cod	Paralabrax nebulifer (Pacific coast). Sebestodes species (Pacific coast). Sebastes marinus.
	(Blue bass, greenfish	Girella nigricans (Pacific coast)
Rudderfish	(Halfmoon	Medialuna californiensis (Pacific coast).
Sablefish	Black cod	Anoplopama fimbria.
Salmon:

## BUREAU OF FISHERIES

FRANK T. BELL, Commissioner

Administrative Report No. 34

# PROPAGATION AND DISTRIBUTION OF FOOD FISHES

FISCAL YEAR 1938

By GLEN C. LEACH, M. C. JAMES and E. J. DOUGLASS

APPENDIX IV TO REPORT OF COMMISSIONER OF FISHERIES FOR THE FISCAL YEAR 1938

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1939

#### ADMINISTRATIVE REPORT SERIES

Since the advent of the Administrative Report Series, considerable confusion has arisen concerning its system of numbering the separates composing it. Inasmuch as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No. —." Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 20 were, they are numbered for filing purposes as follows:

No. 1. Report, Commissioner of Fisheries, 1931.

No. 2. Alaska Fishery and Fur-Seal Industries, 1930. No. 3. Fishery Industries of the United States, 1930.

No. 4. Progress in Biological Inquiries, 1930.

No. 5. Propagation and Distribution of Food Fishes, 1931.

No. 6. Report Commissioner of Fisheries, 1932.

No. 7. Alaska Fishery and Fur-Seal Industries, 1931. No. 8. Fishery Industries of the United States, 1931.

No. 9. Progress in Biological Inquiries, 1931.

No. 10. Propagation and Distribution of Food Fishes, 1932.

No. 11. Alaska Fishery and Fur-Seal Industries, 1932. No. 12. Progress in Biological Inquiries, 1932. No. 13. Fishery Industries of the United States, 1932. No. 14. Propagation and Distribution of Food Fishes, 1933.

No. 15. Fishery Industries of the United States, 1933.

No. 16. Alaska Fishery and Fur-Seal Industries, 1933. No. 17. Progress in Biological Inquiries, 1933.

No. 18. Propagation and Distribution of Food Fishes, 1934. No. 19. Alaska Fishery and Fur-Seal Industries, 1934.

No. 20. Fishery Industries of the United States, 1934.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the Report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

## PROPAGATION AND DISTRIBUTION OF FOOD FISHES, FISCAL YEAR 1938 1

Summary, by States, of fish distribution

#### INTRODUCTION

The production of fish and eggs at Federal hatcheries during the fiscal year 1938 totaled 8,121,131,000. This was very close to the maximum production obtained in 1936 and was a moderate increase over the 1937 record. There are set forth clsewhere in this report the changes in methods and extension of facilities which contributed to this increase.

At no time since practical methods of artificial propagation of fish were developed has there been such a demand by the public for more and larger hatcheries. During this period there has been much critical analysis by biologists of the results obtained from fish-hatchery operations. These trends have resulted in a concerted effort to develop the most efficient and economical methods of conserving or increasing the fishery resources. Until such time as there is a clear-cut formula-

Administrative Report No. 34, Appendix IV to the Report of the U. S. Commissioner of Fisheries for 1938. Approved for publication May 23, 1939.
461

tion of a precise program, it is necessary to view the hatcheries as an implement which has proved its effectiveness in a general way through-

out a period of years.

Broadly speaking, the need for artificial propagation of fish increases as the artificial conditions of fish environment increase. For purposes of this discussion the outstanding element of artificiality may be considered as a concentrated pressure upon the fish stock by the increasing number of anglers or by more intensive commercial fishing. Hence, in many of the thickly populated States practically 100 percent of the take of game fish is of hatchery origin. Even in areas such as the national parks and national forests, there has been an equivalent concentration of angling even though the conditions of the waters themselves have remained virtually unchanged.

The popularization of recreation in many areas has been, in part, based upon an angling pressure far beyond the normal capacity of the streams and lakes to supply. Consequently, the normal, unimpaired productivity of such waters has had to be augmented by stocking.

The other elements of artificiality which have imposed a constantly increasing need for stocking are soil erosion, deforestation, pollution, and the introduction of structures alien to the natural watercourses,

such as flood-control, hydroelectric, and storage dams.

The ultimate benefits to be derived from hatchery operations are as much dependent upon the intelligent use of their production as upon the efficiency with which the hatcheries are operated and the number of fish hatched and reared each season. Consequently, the most fertile field for improvement lies in a better control of stocking

procedure

An interesting aspect of hatchery activities lies in the vague distinction as between game and commercial species. It would be highly desirable if this report could show an analysis, for the benefit of both the sport fishermen and the commercial fishermen, of the production of these two classes of fish. We are at a loss, however, to draw any sharp line of distinction because of the fact that practically all varieties handled at the hatcheries are, under some conditions, sought by the anglers. Even the cod, haddock, flatfish, and pollock are the basis of sport-fishing activities carried on from party boats. It might be said that, out of the 48 species handled, only the lobster, whitefish, lake and glut herring, and two species of Pacific salmon, are completely ignored by sport fishermen. It has, therefore, been virtually impossible to analyze the records of hatchery production so as to show the actual contribution to that portion of the public which fishes for recreation, and to the much smaller group which fishes for a livelihood.

#### SPECIES PROPAGATED

During the year 1938 there were 48 separate species handled at Federal hatcheries, in comparison with 46 species during the previous year. These include the most important game and panfishes, which are foremost in the angler's mind, as well as a number of commercial fish which are most amenable to artificial propagation. Pink, or humpback salmon were propagated for the first time since 1934. Due to unfavorable conditions at the Woods Hole, Mass., station no mackerel eggs were collected this season. With the cooperation of the Montana Fish and Game Department, this Bureau was able to

secure a limited number of landlocked sockeve salmon eggs for hatching.

The following list gives the common and scientific designation of the

species propagated.

Catfishes (Siluridae):

Catfish (Leptops olivaris).
Spotted channel catfish (Ictalurus punctatus).

Bullhead (Ameiurus nebulosus).

Carp (Cyprinidae): Common carp (Cyprinus carpio).

Buffalofish (Catostomidae): Common buffaloes (Ictiobus sp.).

Shad and herring (Clupeidae): Shad (Alosa sapidissima).

Glut herring (Pomolobus aestivalis).

Salmons, trouts, and whitefishes (Salmonidae):

Common whitefish (Coregonus clupeaformis).

Lake herring, cisco (Leucicthys sp.).

Chinook, king, or quinnat salmon (Oncorhynchus tschawytscha).

Chum salmon (Oncorhynchus keta).

Coho salmon, silver salmon (Oncorhynchus kisutch).

Red salmon, sockeye, or blueback salmon (Oncorhunchus nerka).

Pink or humpback salmon (Oncorhynchus gorbuscha).

Landlocked sockeye salmon, silver trout (Oncorhynchus kennerlyi).

Steelhead trout (Salmo gairdnerii). Atlantic salmon (Salmo salar).

Landlocked salmon (Salmo sebago).

Rainbow trout (Salmo irideus).

Black-spotted trout, redthroat trout (Salmo lewisi).

Brown or Loch Leven trout (Salmo fario var.).

Lake trout, mackinaw trout (Cristivomer namaycush).

Brook trout (Salvelinus fontinalis). Golden trout (Salmo agua-bonita).

Grayling (Thymallidae): Montana grayling (Thymallus montanus),

Pikes (Esocidae): Pike and pickerel (Esox sp.).

Sunfishes (Centrarchidae):

Crappie (Pomoxis annularis and P. sparoides).

Largemouth black bass (Micropterus salmoides). Smallmouth black bass (Micropterus dolomieu).

Rock bass (Ambloplites rupestris).
Warmouth bass (Chaenobryttus gulosus).
Bluegill sunfish (Lepomis incisor).

Green sunfish (Lepomis cyanellus).

Redbreasted bream (Lepomis auritus). Red-eared sunfish (Lepomis heros).

Common sunfish (Lepomis gibbosus).

Mojarras de rio (Cichlidae).

Rio Grande perch (Herichthys cyanoguttatus).

Perches (Percidae):

Pike perch (Stizostedion vitreum).

Yellow perch, ringed perch (Perca flavescens).

White basses (Serranidae):

White bass (Roccus chrysops). Striped bass (Roccus saxatilis).

White perch (Morone americana).

Drums (Sciaenidae): Fresh-water drum, lake sheepshead (Aplodinotus grunniens). Cods (Gadidae):

Cod (Gadus callarias).

Haddock (Melanogrammus aeglefinus). Pollock (Pollachius virens).

Flounders (Pleuronectidae): Winter flounder (Pseudopleuronectes americanus). Lobster (Homaridae): Lobster (Homarus americanus).

Summary, by species, of the output of fish and fish eggs during the fiscal year ending June 30, 1938

Species	Eggs	Fry	Fingerlings	Total

#### PRODUCTION

Inasmuch as the total output of eggs and fish varied but slightly from the figure for the previous year, there was relatively little difference in the comparable production of the individual species. The trend of increase in the production of marine commercial species of New England—cod, haddock, pollock, and lobster—has continued.

Other commercial species handled in increased numbers were the shad, lake herring, and buffalofish. The output of all species of Pacific salmon was at a lower level, which accounted, in part, for a reduction in the distribution of fish of the fingerling size. There was a slight increase in the distribution of steelhead trout, so popular on the Pacific coast.

The production of largemouth and smallmouth bass, approaching 70 million fish, exceeded all previous records for these species. The aggregate number of trout and trout eggs, which contributed to the development of good angling, was 99 million. Grouping the so-called "panfishes" with the strictly game varieties, there was a total production of 131½ million fish of a noncommercial type.

While this report emphasizes the number of fish and eggs produced, there has been an unremitting effort to maintain the existing high quality of stock.

#### CONSTRUCTION ACTIVITIES

Major construction activities were concerned with the establishment of four new hatcheries, as authorized by the act of May 21, 1930. The 1938 appropriations act carried an item of \$155,000 for this purpose. The new hatcheries were, by law, allocated to the States of Florida, Nevada, Georgia, and Mississippi. After a careful preliminary survey the Secretary of Commerce approved locations at Marianna, Fla., Las Vegas, Nev., Cohutta, Ga., and Lyman, Miss.

The delay incident to acquiring title to the sites deferred the starting of actual construction until late in the year and none of the establishments were completed at the close of the year. However, a limited number of fish were produced at Lyman, Miss. The Nevada project consisted of a small hatchery which had been previously operated by the city of Las Vegas. This was donated to the Bureau and a program of enlargement and improvement was undertaken. One other site was also acquired by donation. All hatcheries were developed to the point where they were in readiness for some fish production during the fiscal year 1939. All of these hatcheries will produce warm-water species.

At Carson, Wash., the development of a trout and salmon hatchery, started in the fiscal year 1938, was continued until the exhaustion of available funds. A hatchery, service buildings, water-supply system, and several dwellings for personnel were provided, leaving a

further need for rearing ponds.

During the year the Farm Security Administration transferred to the Bureau of Fisheries a site at Arcadia, R. I., for development as a bass hatchery. Preliminary development work on a cooperative basis with the Farm Security Administration was undertaken, but the major part of the construction remained to be done during the

succeeding fiscal year.

Some repairs and improvements at the older hatcheries were effected by the setting up of local W. P. A. projects. The most important of these were for the complete rehabilitation of the Hartsville, Mass., and the White Sulphur Springs, W. Va., stations. By the utilization of funds from the regular appropriations as a sponsor's contribution, it is possible to carry out extensive improvements

under such procedure.

At the close of the fiscal year there had been approved an allocation of \$808,500 from the Public Works Administration, and \$500,050 from the Works Progress Administration. These amounts, which were to be disbursed by the Bureau, covered a broad program of improvement and enlargement at practically all of the hatcheries, the purpose being to put all of the properties in the best possible physical condition and thus add materially to their operating efficiency. No work had started on these projects at the close of the fiscal year.

#### COOPERATION WITH OTHER CONSERVATION AGENCIES

Among the administrative procedures most valuable in conducting the Federal fish-cultural activities may be listed the cooperative relations existing with other agencies working in the same field. No other Federal agency has the responsibility of operating hatcheries, but numerous bureaus of the Federal Government administer lands and waters which receive the output of the hatcheries maintained by this Bureau. Such agencies as the Forest Service, National Park Service, Bureau of Reclamation, Office of Indian Affairs, and various other land-administering units, have encountered problems in fish management

and stocking in areas under their control.

Whether or not formal agreements of cooperation, such as have been drawn up with the Forest Service and the Tennessee Valley Authority, have been put into effect, the Bureau has contributed to the solution of these problems. The Division of Fish Culture assisted the T. V. A. in the preparation of plans for a large hatchery on the Elk River in Alabama and at the close of the year construction opertions were being started. Upon completion, this unit is to be operated by this Bureau.

In the Chattahoochee National Forest a very complete troutrearing unit was constructed by the Forest Service and turned over to the Bureau of Fisheries for operation. Several similar establishments are operated in other national forests, generally on a seasonal basis. In the general distribution from regular hatcheries special attention has been given to the requirements of the Forest Service.

Late in the fiscal year the Forest Park Hatchery, located in the municipal park system of the city of St. Louis, was abandoned by the State Conservation Department due to insufficient funds for its operation. The Bureau was requested to take it over temporarily under agreement with the city. An experienced fish culturist was assigned to take charge and a successful hatching season resulted, although the greater part of the fingerling bass, panfish, and other species were retained for later distribution. The Bureau has also maintained a man at a State hatchery located at Palestine, W. Va. Lobster culture at the Bureau's Gloucester, Mass., station was conducted in cooperation with the State Division of Marine Fisheries and plans are being developed for a comparable effort in lobster culture jointly with the State of Maine.

The Bureau prepared plans for the development of a bass hatchery at Inks Dam, Tex., on the lower Colorado River. The site was made available by the Lower Colorado River Authority, with the labor to be furnished by the National Youth Administration. Active development work was starting at the close of the year, with the intent that the establishment would be operated by the Bureau upon completion.

A similar establishment was in process of construction at Elephant Butte Dam, N. Mex., the sponsoring agency being the Bureau of Reclamation, with labor furnished by the Civilian Conservation

 $\operatorname{Corps}$ .

As heretofore, the closest contact with the State fish and game departments has been in the distribution of the hatchery output and in the exchange of eggs. The fact that, as a general rule, the public recognizes no distinction between State and Federal hatcheries and their activities, is indicative of the high degree of unity which has been achieved.

The Bureau's contacts with private and semipublic sportsmen's and conservation organizations have been largely in the nature of direct services. Such organizations have been recipients of large numbers of fish for stocking and have been furnished with technical advice when needed. As an example, there may be cited the hatchery development at Carpenters Brook, Onondaga County, N. Y. Local sportsmen enlisted the aid of the county authorities and county funds

were used as a sponsor's contribution for the setting up of a W. P. A. project. This is resulting in the establishment of a first-class trout and bass hatchery, for which the Bureau is supplying eggs and fish, as well as technical operating guidance. The existing establishment at Rochester, N. Y., has served as a successful model for the newer

Field employees of the Division of Fish Culture have been inculcated with a will to cooperate and this attitude has been largely reciprocated. An exhaustive itemization of all phases in which coordination has resulted in efficiency and economy would be too

extensive for treatment in this report.

#### SALVAGE OPERATIONS

Rescue crews were sent into the field at five different points within the territory of the Upper Mississippi Wild Life Refuge for the purpose of salvaging fish stranded in sloughs. In handling 43,194,485 fish the collections were approaching the normal average of preceding years, although the scope of the work is being progressively reduced by the development of the area for navigation. Approximately 1.2 percent of the fish rescued were utilized for general distribution, the remainder being returned directly to the Mississippi River. The requirements for distribution in interior waters were largely met from the production of propagating ponds of a semiartificial nature.

Several carloads of the rescued fish were assigned to the State of North Dakota for the purpose of stocking new lakes and reservoirs. The State defrayed the transportation charges. As the character of the Upper Mississippi Wild Life Refuge has changed through improvement of navigation facilities, there has been corresponding change in the fisheries' administrative problems. The period of survey and salvage activities has largely passed, and future work will be directed toward the development of propagating ponds, several of which can be advantageously located immediately below the navigation dams.

#### ASSIGNMENTS OF FISH AND FISH EGGS TO STATES, TERRITORIES, AND FOREIGN COUNTRIES

Six foreign countries and the Territory of Puerto Rico were the recipients of fish or fish eggs produced at Bureau hatcheries. Each year there are requests for the acclimatization of American food and game fishes in foreign countries. A number of the shipments referred to in table 3 were in continuation of programs previously started. The Bureau has for several years supplied raw material in the form of fish eggs or fingerling fish for the hatchery operated by the Puerto Rican Department of Agriculture. Rainbow eggs shipped to Venezuela were to augment a previous consignment from which a large part of the fish were lost after their successful hatching in Venezuela.

It will be noted that the rainbow trout was the most popular species, due to the hardiness and adaptability of this member of the

trout family.

Both the Mexican and Argentine Governments now operate their own hatchery facilities and the egg shipments made by the Bureau were as a measure of cooperation with these countries. Lake-trout eggs were shipped to Switzerland a number of years ago and their successful development in certain Alpine lakes prompted the Swiss Government to request a further consignment. The assignment of one-half million brook-trout eggs to Canada was on an exchange basis, since the Bureau was the recipient of an equal number of lake-trout eggs in compensation.

The problems attending foreign shipments of eggs and fish, particularly to distant points, are many, but it is believed, particularly in the case of the American republics, that the special effort required is justified as a step toward better international understanding.

The Bureau has been able to assign eggs, fry, and fish to several of the States. By such arrangement the activities of the State hatcheries are greatly benefited. Many of the assignments shown in the table above were not, of course, outright donations, but were transfers which made it possible for Bureau applications to be filled from State hatcheries, and the cost of distribution was thereby reduced.

The comparatively large assignments of rainbow-trout eggs, fingerlings, etc., were due to the fact that the Bureau is the principal source of supply of eggs from the fall-spawning strain. These eggs are in great demand because of the fact that their early hatching results in much larger fish for distribution during the spring months.

The total number of our assignments was somewhat below the record of the previous year, due, among other reasons, to the failure of our supply of Loch Leven trout eggs.

#### TRANSFER OF EGGS BETWEEN STATIONS

As equipment is transferred between the various units of the Bureau's hatchery system for the purpose of more effective utilization, so are surplus eggs of one hatchery shipped for incubation at

other points. Natural conditions favor the production of eggs of certain species of trout at certain hatcheries, and economy requires that these favoring circumstances be taken advantage of. Such shifting of the egg supply is also considered a measure of distribution, since eggs can be shipped for a long distance quite economically, whereas the transportation of fish of a stocking size might represent an expenditure of hundreds of dollars.

#### STATION OUTPUT

There has been a continuation of the development of new fish-cultural facilities, and the 1938 output was obtained from a total of 49 main stations and 43 substations. Among the units which contributed for the first time to the distribution listing were the establishments at Carson, Wash.; Elephant Butte, N. Mex.; and Forest Park, St. Louis, Mo. The Pisgah Forest, N. C., station, which is a fully equipped rearing unit, also entered into production for the first time. The output of the Rochester, N. Y., cooperative establishment is likewise listed because of the fact that the Bureau is responsible for the operations of this establishment.

The San Angelo, Tex., station produced 102,000 pondfish in its first season's activity. The Walhalla, S. C., station did not hatch any trout but, from fingerlings transferred there for rearing, a distribution of 77,000 fish was obtained. Although the Bureau took over the Welaka, Fla., station virtually at the onset of the spawning season, it was, nevertheless, possible to achieve a distribution of

300,000 largemouth bass before the close of the year.

Fish-cultural work was discontinued at Lakeland, Vt., where formerly pike perch and yellow perch had been propagated in coop-

eration with the State of Vermont.

The Bureau has followed the practice of listing as distributed all fish which were transferred from its hatcheries to rearing units operated by private organizations or by States. When fish have been transferred to the Forest Service rearing projects, where the Bureau maintains a measure of supervision and actively participates in the distribution, the production figures are those which cover the actual number of large fingerlings planted at the close of the rearing season. It has been found impracticable to attempt to follow through to the ultimate stocking performed from rearing projects which are supervised by agencies other than the Bureau.

It is timely to repeat a statement which has appeared in previous Divisional reports relative to the distribution of carp. All carp eggs

which the Bureau's hatcheries handle are secured in sections where there is an active commercial fishery for this species and they are not distributed elsewhere.

#### EGG COLLECTIONS

Egg collections during the fiscal year 1938 exceeded those of 1937 by approximately 70,000,000 eggs. As usual, the greater percentage of the collections comprised the four marine species; namely, cod, haddock, pollock, and flounder. The greater part of the eggs of these species is secured from fish caught by commercial fishermen. These eggs are fertilized and returned directly to the spawning grounds.

The recession in the take of Loch Leven trout eggs was due to the

The recession in the take of Loch Leven trout eggs was due to the draining of the hydroelectric reservoir in the Madison Valley where

these eggs are obtained.

The following table presents a comparison of the 1938 and 1937 collections:

Comparison of egg collections, fiscal years 1937 and 1938

#### NOTES ON OPERATIONS

#### COMMERCIAL SPECIES

Pacific salmon.—The output of chinook, chum, silver, and sockeye salmon from the Pacific coast hatcheries was below that of last year. This was due to the decline in the take of eggs. Humpback salmon were handled for the first time since 1934. At the Clackamas, Oreg., station, and its auxiliaries, more than 20,000,000 chinook salmon eggs were collected. The collections at Mill Creek and Battle Creek substations were practically quadrupled over last season. was ascribed to heavy rains and high water during the entire season. permitting an unusually heavy run of fish. The acquisition of the Delph Creek rearing station by transfer from the Oregon State Game Department is proving to be a valuable addition to fish-cultural activities of the Clackamas, Oreg., station. Chinook salmon and brook trout were both reared at this point. The Butte Falls, Oreg., substation collected approximately 2,000,000 chinook salmon, 80,000 silver salmon, and 113,000 steelhead trout eggs. Two new residences are under construction at this point.

The Little White Salmon and Big White Salmon, Wash., substations were largely engaged in the propagation of chinook salmon. At the former station 9,775,000 eggs were collected, while at the latter 8,640,000. The take of eggs at both of these units was below that of last year, correlated, of course, with a reduction in the run of Reestablishment of the Big White Salmon station was carried on under the auspices of the United States Army Engineers, as a part of the Bonneville Dam project. Buildings were moved and ponds

rearranged.

In the Puget Sound territory the Birdsview, Wash., station collected 6,700,000 salmon and trout eggs and received by transfer 1,280,000 eggs. These eggs comprised the five species of Pacific salmon and four varieties of trout. Gratifying results have been attained in establishing new runs of sockeye salmon where fingerling fish of this species were liberated during 1934 and 1935. The largest run of humpback salmon in the past 25 years occurred in the Skagit River and its tributaries during the fall of 1937.

No fish-cultural operations were carried on at the Baker Lake, Wash., substation. The salvaging of material from the hatchery building, which collapsed under heavy snow February 22, 1937, and the remodeling of the sawmill building into a hatchery, was carried on by C. C. C. enrollees. This station, which was formerly used for the propagation of salmon, will now be used for rearing trout to stock the waters of Mount Baker National Forest.

The Mount Rainier, Wash., substation collected and received from other stations approximately 1,000,000 trout eggs of various species. Most of the resulting fish were liberated in waters of Mount Rainier National Park and the Snoqualmie National Forest. From the rearing ponds at Spokane, Wash., 300,000 large fingerling trout and graylings were distributed. Most of these fish were assigned to

the Conservation Departments of Washington and Idaho.

In the Olympic Peninsula, the Quinault, Wash., hatchery collected 2,000,000 sockeye salmon eggs instead of the yearly average of 10,000,000 and reared the entire output of both salmon and trout to larger fingerlings before liberating them. The dam from which the

hatchery receives its water supply was rebuilt.

The substations located at Duckabush and Quilcene, Wash., concentrated on the propagation of chum salmon, but a number of other species of salmon and trout were also handled. The steelhead trout run in the Duckabush River was very small and no effort was made to collect the eggs of this species.

#### MARINE SPECIES

The Woods Hole, Mass., station collected 506,824,000 winter flounder eggs and distributed 452,663,000 fry. In view of the favorable reports from previous plants of flounder fry in Long Island Sound and Narragansett Bay, a number of fry were planted in these waters, but the largest percentage were liberated in the coastal waters of Massachusetts. Several hundred feet of steam pipe between the boilerhouse and hatchery building was renewed. The Massachusetts Department of Conservation was allowed the use of space in the hatchery for the purpose of carrying on an experiment in the feeding and rearing of young lobsters. During June, 94,600 lobster fry were liberated.

At the Gloucester, Mass., station several spawn-takers were placed aboard commercial fishing vessels for the purpose of collecting haddock, pollock, cod, and flounder eggs. The total number of eggs taken exceeded 5,112,000,000, which was more than 16 percent over that of 1937. Of this number, slightly over 626,000,000 were propagated at the hatchery. The balance, after fertilization, were planted directly on the spawning grounds. The lobster-cultural work was carried on in cooperation with the Massachusetts Department of Conservation. From 273 seed lobsters approximately 2,503,000 eggs were taken and placed in hatching jars and 300,000 young lobsters in the fourth larval stage were liberated in Massachusetts coastal waters. Experiments in the feeding of fish instead of meat to lobster fry were carried on. Of the several kinds of fish fed, haddock seemed to be the most

The Boothbay Harbor, Maine, station collected cod, haddock, and flounder eggs. The eggs of the two former species were fertilized and

returned to the natural spawning grounds, while the flounder eggs were hatched with a loss of only about 10 percent. The number of eggs taken from adult flounders averaged approximately 243,000 per fish, but, due to the development of slime on the spawning grounds and the disappearance of eelgrass, the station was unable to collect as many spawners as heretofore. In cooperation with the Department of Sea and Shore Fisheries of Maine, lobster culture was continued. On account of the low water temperature, coupled with the cannibalistic tendencies of this crustacean, it has been a difficult task to hold the fry until they have reached the fourth stage. However, experiments are being conducted in the heating of the hatchery water. While it is too early to reach any definite conclusions it appears that by heating the water 12 to 15 degrees, lobsters can be reared to the fourth stage in 11 to 13 days with a loss of only about 50 percent, while about only 15 to 20 percent would reach this stage under natural water temperatures.

#### GREAT LAKES SPECIES

Except at the Put-in-Bay, Ohio, station, the propagation of commercial species of the Great Lakes continued on a restricted basis. As the closed season on lake trout was set ahead to October 1, the Duluth, Minn., station was unable to secure any eggs of this species from the early runs of fish. After the closed season some lake-trout eggs were received from the commercial fishermen, and the State of Michigan, but, due to the scarcity of fertile males at this time of the year, the percentage of hatch from these eggs was very low. were 7,870,000 whitefish eggs handled during the season and 5,000,000 of this number were allotted by the State of Minnesota. More than 1,000,000 lake-herring fry were planted in the inland lakes of the Superior National Forest. The output of pike perch from the Duluth station was greatly increased over that of 1937. gation of this species was carried on in cooperation with the Minnesota Conservation Department, fish being liberated in the waters of that State. Of the 61,500,000 eggs handled, 50,000,000 were collected by the State. In addition to the propagation of the above commercial species, the station hatched Loch Leven, brook, and rainbow trout for the supplying of rearing stations in the national forests.

The collection of pike-perch eggs at the Put-in-Bay, Ohio, station was considerably below that of last season, as weather and water conditions were unfavorable during the entire spawning period. However, approximately 256,000,000 eggs were collected from the various fields. In addition to the pike-perch work, more than 120,000,000 whitefish eggs were handled. The propagation of both species was conducted on a joint basis with the State of Ohio.

The output of commercial species from the Cape Vincent, New York, hatchery was relatively insignificant. All whitefish and laketrout eggs handled were received from local and Canadian fishermen with the exception of 500,000 lake-trout eggs received from the Province of Ontario in exchange for brook-trout eggs from the York Pond hatchery. There was no active work at the Swanton, Vt., substation which had previously handled pike perch and yellow perch.

To supplement the Cape Vincent output, rainbow, brook, and Loch Leven trout and smallmouth black bass were propagated.

activities of this station with regard to its output of game fish and operation of its substations will be discussed elsewhere in this report.

#### ANADROMOUS SPECIES, ATLANTIC COAST

This is the first year since the early 1880's during which no Atlantic-salmon eggs were hatched. This was due to inability to secure eggs from Canada, coupled with the fact that there is no local source of supply of these eggs at any of our hatcheries. The Craig Brook, Maine, station liberated 77,500 fingerlings which were reared from eggs hatched in 1937.

The Fort Belvoir, Va., station increased its output of both shad and yellow perch. Approximately 330,000,000 yellow perch and 15,000,000 shad were liberated in the Potomac River and its tributaries. Two docks that were wrecked while the station grounds were inundated by

the Potomac River were repaired and creosoted.

The Edenton, N. C., station reported the largest output of shad since the season of 1922. From 10,481,000 eggs more than 7,000,000 fry were hatched. All of these were planted in Albemarle Sound and its tributaries, with the exception of 581,000 which were placed in hatchery ponds for investigation and study. Fry placed in the ponds the latter part of April were 2 inches long the first part of July. Experiments in the rearing of striped bass were also carried on. The study of factors concerning the conservation of shad was continued in cooperation with the State of North Carolina. A total of 7,221,000 yellow perch, white perch, and herring fry were hatched and liberated in local waters. The station supplemented its work with commercial varieties by propagating pondfish for the stocking of inland waters. Under a W. P. A. project, six more ponds are being built and the present reservoir enlarged. Daphnia ponds and a new residence and garage are also being constructed with the cooperation of this agency.

The Weldon, N. C., station was again operated for the hatching of striped bass on a joint basis with the Conservation Department of North Carolina. The take of eggs was below that of 1937, but the percentage of hatch was much greater. The fry were strong and

vigorous.

Supplementing its pondfish activities, the Orangeburg, S. C., station again operated the Jacksonboro shad hatchery located on the Edisto River. The total collection was in excess of 1,204,000 eggs. While this number is considerably below that of some of the better seasons, it does represent a substantial increase in production over the past several years.

#### GAME-FISH PROPAGATION

As reduction in the average working day allows more time for recreation, the number of man-days of angling is increasing rapidly. Consequently the demands upon State conservation departments and the Bureau for the furnishing of more and larger game fish for the restocking of inland lakes and streams have increased accordingly. Likewise, there is a big demand for the stocking of waters recently impounded by various Federal agencies such as the Soil Conservation Service, and the Bureau of Reclamation. The Bureau's entire out-

put of game fish could advantageously be utilized in the stocking of waters solely under Federal control. In fact, in some of the public lands, hatcheries are operated solely for the restocking of waters within the boundaries of such areas. Biological surveys have also been conducted in a number of public domains and stocking programs drawn up. In an effort to rear the output of fish to a larger size before liberating them, with the available funds, a number of experiments in the feeding of cheaper foods such as various types of meal, frozen fish, and offal from animals and fish have been carried on. Of the 92 Bureau hatcheries that were on a productive basis this season, all but 13 handled one or more species of game fish. However, most of these units are engaged solely in the propagation of game varieties. Strictly game and pan species distributed from these stations numbered 160,655,000 during the fiscal year, which was an increase of more than 34,000,000 over that of the previous There was a definite increase in the production of 11 different varieties of game fish. Included in these were the largemouth and smallmouth black bass and all the main varieties of trout except Loch Leven. The following data covering the activities of the individual stations will, however, give a better understanding of the nature of the season's work.

#### ROCKY MOUNTAIN TERRITORY

Inasmuch as the activities at the Yellowstone Park station continued into parts of 2 fiscal years, the following data cover the summer of 1937. All previous egg-collection records for blackspotted trout, Montana grayling, and rainbow trout were broken in this field. A grand total of 47,341,960 eggs was collected, of which number 70 percent were used to restock park waters. Electrical fences were used at several of the trap sites to protect adult trout from bears during the spawning season. All suckers caught in traps were utilized for fish food or destroyed. This season marked a new high in tourist travel in Yellowstone Park and fishing was reported better than during the previous year.

At the Springville, Utah, station, 2,672,000 rainbow eggs were collected from brood stock. This station also handled brook, blackspotted, and Loch Leven trout, grayling, and a limited number of

The Bear Lake substation reported a normal production of five species of trout. W. P. A. employees were engaged in making various improvements to buildings, ponds, and grounds.

Although the Elephant Butte, N. Mex., station was incomplete, a good production of bass and sunfish was obtained from the few ponds

The Dexter, N. Mex., station's output of pondfish exceeded that of any previous year, over 1\% million fingerling fish being distributed. Most of these were handled by the New Mexico Department of Game and Fish under the same agreement as heretofore. Three small buildings were constructed, ponds excavated, and various other improvements made to station buildings, water-supply system, and grounds, under the auspices of W. P. A.

The output of the Santa Rosa, N. Mex., substation was limited

because the ponds were too unproductive of food organisms to pro-

duce more than a nominal output of fish. Pond bottoms were fertilized at intervals to overcome this situation.

The water temperature at the Glacier Park, Mont., station was so low that all fish hatched from the 2,000,000 black-spotted-trout and 250,000 rainbow-trout eggs received from the Yellowstone Park were

planted in the fry stage.

In the Montana field, the Bozeman station distributed approximately 4,000,000 fry and fingerling trout and grayling. The greater percentage of this output was utilized in restocking waters under Federal control. The experiment in the rearing of Montana grayling fry to fingerlings proved very successful. The following construction work was made possible by two W. P. A. projects: Three-stall addition to the garage, construction of two new concrete rearing ponds, painting of all buildings, graveling of driveways, cutting fire lanes through forest areas, laying of drains, and many miscellaneous repairs and improvements.

The collection of Loch Leven trout eggs in Madison Valley again fell to a new low. The Ennis, Mont., substation collected, at its four spawning camps, less than 400,000 eggs of this species. However, one-half million eggs of this variety were furnished this station by the Montana Department of Fish and Game for hatching, rearing, and planting in the Madison River and its tributaries in an effort to reestablish Loch Leven trout in this watershed. Although this station is in an incomplete status, approximately 5½ million eggs, fry, and

fingerlings were distributed.

Considering the shortage of brood stock and the water levels of the lakes, the production of pondfish was satisfactory at the Miles City, Mont., substation. The output of bass was slightly lower than during the previous season but the difference in numbers was offset by the size of the fish. The production of catfish was in excess of any previous year in the history of the station.

In the Idaho territory, the Hagerman station reared its output of 1½ million trout to large fingerlings before releasing them. Extensive repairs and improvements, including the enlarging of the feed storage room, were made possible by assignment of W. P. A. employees.

The Salmon, Idaho, substation was operated during the summer months, in cooperation with the Idaho Fish and Game Department, as a base for handling the rainbow trout eggs collected at Williams Lake. The total collection for the season was slightly in excess of 4,000,000.

In the Colorado field, the Leadville station continued to cooperate with private parties in the collecting of trout eggs. The percentage the Bureau retains depends largely upon the manner in which the activities are carried on. However, the Bureau received several million eggs from such sources. The substation at Crystal Lake was utilized as a rearing unit. At the Eagle Nest, N. Mex., substation, which is operated during the summer months, approximately 2,000,000 rainbow-trout eggs were collected from Eagle Nest Lake by seining the beach for spawners. Owing to the large number of suckers ascending the creeks, this method of obtaining adult trout was necessary.

The Creede, Colo., substation collected 3,285,000 brook-trout eggs from Lake San Cristobal. These eggs were of excellent quality, eveing up approximately 98 percent and producing vigorous and healthy fingerlings. There were 3,000,000 brook-trout eggs received from commercial trout dealers for eveing or hatching on a cooperative basis.

The Bureau received a large quantity of eggs at a very small cost by such cooperative arrangements. A new electric-light plant was installed.

No major improvements were made at the Saratoga, Wyo., station, and the output of fish and eggs was practically the same as during the

previous year.

At the Spearfish, S. Dak., station, over 1,258,000 rainbow- and 610,000 brook-trout eggs were collected from station brood stock. which is the largest collection ever made in the history of this unit. This station was again the beneficiary of a W. P. A. project which permitted the installation of several badly needed supply and drainage lines and the installation of five additional hot-water heaters for heating the water utilized in the hatching of eggs as a means of shortening the incubation period. N. Y. A. girls assigned acted in the capacity of guides showing visitors about the station and explaining the Bureau's work.

#### NEW ENGLAND TROUT STATIONS

The Nashua, N. H., station carried on its activities in a normal manner and achieved an average production of three species of trout.

Until the development of furunculosis the latter part of the year, the National Forest, N. H., station had the most successful year in its history. More than 14% million brook-trout eggs were collected, of which number approximately 10 million were shipped to State conservation departments and other Bureau stations. repairs and improvements were made with W. P. A. and C. C. C. labor. New water-supply lines were laid and several new ponds were constructed. A new electric generator was installed in the power plant. New Hampshire and Vermont contributed funds for the purchase of fish food in order that the fish could be reared to a larger size before liberation in the waters of their respective States. Gratify. ing results were obtained from the feeding of cheaper foods such as blood, beef brains, pork melts, horse meat, ground fish, fish spawn, and offal.

The York Pond station is so laid out that isolation of disease, such as furunculosis, is impossible. Accordingly, it was decided to destroy all fish on hand and sterilize the entire plant. Chlorine was selected as the most satisfactory and efficient agent for the purpose, and at the close of the year this distressing but necessary project was under way. None of the infected fish were planted, and if it is possible to eradicate completely a furunculosis infection the measures taken at York Pond

will undoubtedly accomplish this result.

The major activity at the St. Johnsbury, Vt., station was the hatching and rearing of brook trout. Approximately 1½ million of this species were handled and also several thousand landlocked salmon, brown trout, and black bass. All three of the latter species were furnished by the State of Vermont. New cement raceways and cement bulkheads to ponds were constructed with W. P. A. labor. hatchery foundation was also reconstructed during the year.

The Pittsford, Vt., station continued its experiments in selective breeding of trout. This season the breeders yielded eggs at the rate of 1,369 per pound of fish, which is 37 percent over the accepted rate per pound of trout. The general condition of the buildings and

grounds was greatly improved by W. P. A. employees.

The Hartsville, Mass., station handled its normal quota of trout, of which several thousand were consigned to eight cooperative nurseries operating in Massachusetts and Vermont. There were 778,000 small-mouth black-bass fry collected from Wangum Lake in cooperation with the State of Connecticut under the same agreement as heretofore. Eight circular trout pools 22 feet in diameter are being constructed under the auspices of W. P. A.

In Maine the Craig Brook station collected 3½ million brook-trout eggs, of which number approximately 2 million were shipped to other Bureau units. A limited number of rainbow and lake-trout fingerlings were distributed. The Acadia National Park was furnished 105,000 large fingerling fish to compensate them for the construction of circular rearing pools built at this station. The old plank conduit

from the spring was replaced with a new iron soil-pipe line.

#### COMBINATION TROUT AND PONDFISH STATIONS

Owing to the overlapping of the range of trout and warm-water species, such as bass, a number of hatcheries propagate both. However, most of the establishments in this category are principally concerned in the propagation of trout, and the output of pondfish is very limited.

At the Leetown, W. Va., station, a reservoir and 20 ponds, 50 feet wide and varying in length from 150 to 600 feet, were excavated. The concrete dam and outlet box for the reservoir and the necessary kettles for these ponds were also constructed. Several thousand trout 5 inches long were distributed, most of which were released in the waters of the Monongahela and George Washington National Forests. Experiments in the feeding of various kinds of food to adult trout were carried on in order to determine the effects of different diets upon the quality of the eggs. Experiments in the stocking of warm-water rearing ponds with blunt-nosed and black-head minnows and golden shiners were conducted for the purpose of determining how many of the above forage minnows should be stocked per acre of water.

The selective breeding of rainbow trout was continued at the Neosho, Mo., station. This selective breeding has accomplished one object in that during the last season more eyed rainbow eggs were produced from a smaller number of brood stock than in any previous year in the history of the station. The output of pondfish approximated the normal average. The culture of daphnia magna was

successfully carried on during the spring months.

At the Bourbon, Mo., substation, operated on a cooperative basis, the production of rainbow-trout eggs was approximately 50 percent in excess of last season and 10 percent more than any previous year.

The pond system has never been completed at the Flintville, Tenn., station, consequently the propagation of pond species is limited. The output of trout was normal and sufficient to take care of the demands in that territory. N. Y. A. employees built picnic areas for the benefit of the visiting public.

The operations at the Erwin, Tenn., station were largely of a routine nature, and the production of trout and pondfish was comparable to

that of last year.

The Cape Vincent, N. Y., station, and its substations at Cortland, Watertown, and Barneveld, contributed approximately 2 million trout

for the restocking of New York waters. The output of smallmouth black bass at Cape Vincent was 20 percent in excess of last season. Several cooperative nurseries, located throughout the State of New

York, were supervised.

In addition to handling a limited number of pondfish, the White Sulphur Springs, W. Va., station distributed 1,600,000 trout. Most of these were planted in the waters of West Virginia in cooperation with the State Conservation Commission. W. P. A. employees were engaged in enlarging ponds and landscaping the surrounding grounds.

The Rochester, N. Y., station, which was operated in cooperation with Monroe County, reared the greater percentage of its output of trout to legal size before liberating them in waters under the control of the county park officials. Several thousand bass were also pro-

duced for the stocking of Monroe County waters.

In addition to a normal output of trout and pondfish, the Wytheville, Va., station received 525,000 pike-perch eggs and planted the resultant fry in New River. The propagation of largemouth black bass was discontinued. The pond space which was heretofore utilized for the handling of this species was used for rearing smallmouth black bass which are more in demand for the stocking of surrounding waters. Several thousand rainbow and brook-trout fingerlings were assigned to the States of North Carolina and Virginia.

At the Lamar, Pa., station, and its auxiliary at Ogletown, approximately one-half million trout were reared and released in the waters of western and central Pennsylvania. In order that this station can collect and hatch its own eggs, a hatchery building is being constructed. C. C. C. labor was utilized in the construction of this unit and the landscaping of the surrounding grounds. A site for bass ponds was

cleared.

Five cooperative feeding stations, handling approximately 700,000 trout, were operated under the direction of the Northville, Mich., station. The output of pondfish was in excess of 100,000. At the close of the year a new wall between the spring reservoir and the

highway was being constructed by W. P. A. employees.

The output of the Manchester, Iowa, station varied but little from that of last year. Of the 11/2 million rainbow trout eggs collected, approximately 11/4 million were shipped to other Bureau and State hatcheries. The output of pondfish was again very small. All station buildings were given two coats of paint by W. P. A. employees.

#### APPALACHIAN AND BLUE RIDGE TROUT STATIONS

As the Walhalla, S. C., station was incomplete at the beginning of the season, it was necessary to ship in trout from other points for rearing purposes. Consequently, only a limited number of trout were handled and they were planted in the waters of the national forests. The hatchery building was completed during the early fall which enabled this station to incubate eggs for the first time. There were 1,000,000 brook and rainbow trout eggs handled and, at the close of the year, there were on hand approximately 750,000 fish from these The Forest Service rearing stations at Franklin, N. C., and Clayton, Ga., are under the jurisdiction of this station.

The Smokemont, N. C., station, which is operated for stocking the Great Smoky Mountain National Park, reported a normal production of brook and rainbow trout. At the close of the year 470,000 fingerling trout were being reared in various ponds throughout the park area for

fall distribution.

The Pisgah Forest, N. C., station, operated solely for the stocking of waters in the Pisgah National Forest, reared the greater percentage of its output of trout to legal size before releasing them. However, considerable risk is taken in carrying fish through the winter at this station because of the probability of their succumbing to the effects of anchor ice. This station handled brook, rainbow, and brown trout.

#### PONDFISH STATIONS

The bass, sunfish, and other warm-water species are extremely prolific, but even in areas of their greatest natural abundance there is evidence of depletion. Intensive angling probably contributes most to this depletion. Consequently the demand for these species of fish is constantly increasing. In an effort to keep pace new units are being constructed, and pond acreage at a number of the old establishments is being extended. Additional pond space is the most essential factor for increasing the output of the warm-water species. However, the production is somewhat at the mercy of weather and other conditions

over which there is no control.

Six ponds were constructed at the Marion, Ala., station, adding 22 acres of water to the pond system. Improvements were made in other ponds by removing dirt from shallow areas and utilizing it to reinforce levees. Three concrete pools were built for the purpose of propagating daphnia and holding fish during the distribution season. The metal tanks at the shipping shed were replaced with concrete ones. Weather conditions during the bass spawning season were more favorable than last year; consequently the output of this species was materially increased. A total of 752,050 bass were handled. The number of bream delivered to applicants was less than last year, but a greater poundage of this species was distributed, as the fish were practically twice as large. Efforts to propagate crappie and rock bass were largely unsuccessful.

There was no spring distribution at the Lyman, Miss., station. However, several thousand black bass fry were transferred to rearing

ponds for fall distribution.

At the Tupelo, Miss., station a new drainage line was laid to four ponds. Over one-half million fingerling black bass and bream were distributed. This station's pond acreage is limited and the above figures represent a production of approximately 31,000 bass and 21,000 fingerling bream per acre.

The Division of Wild Life of the State of Georgia distributed most of the fish produced at both of the Georgia stations. The total production of largemouth black bass, sunfish, and catfish from these two units was practically the same as last season. Repairs were made to

pond levees at both stations.

Despite the fact that the pond area at the Orangeburg, S. C., station was reduced, due to the construction of the concrete canal through the hatchery grounds and the reconditioning of pond bottoms, the production of fish, although less than that of last year, was on a level with the average yearly output. The greater portion of the crop was largemouth black bass and bluegill sunfish, but a limited number of

red-eared and redbreasted sunfish, crappie, catfish, and warmouth bass were distributed to applicants. In addition to the above, construction work was carried on. Station buildings were repaired and

painted as a W. P. A. project.

Although the Hoffman, N. C., hatchery was under construction during the entire year, 11 one-acre ponds were completed and utilized for producing black bass, warmouth bass, sunfish, and crappie. The output from these ponds was 449,000, of which all were fingerlings except 56,000 bass fry. Many of these were utilized in stocking ponds and lakes of the land utilization project in which the hatchery is located.

The pond acreage at the Mammoth Spring, Ark., station was not increased but the output of fish was much greater than normal. The distribution of the four species propagated was in excess of 740,000. Smallmouth black bass fry were consigned to both the Arkansas and

Missouri conservation departments.

At the Louisville, Ky., station the rehabilitation of buildings and grounds which were severely damaged by the 1937 flood was completed, including the excavation of a new pond. This station was favored with a W. P. A. project to assist in this work. The production of fish was below that of normal years but was in excess of that of the previous season. Brood stock was collected from local waters to replace that lost during the flood.

Although the Uvalde, Tex., station was under construction during the entire year, approximately one-half million black bass were pro-

duced and liberated in local waters.

The output from the San Marcos, San Angelo, and Forth Worth,

Tex., substations was slightly in excess of that of last season.

The Welaka, Fla., station was received by transfer from the Farm Security Administration the latter part of the year. During the 3-month period that this unit was operated by the Bureau, 120,000 fry and 180,000 fingerling bass were distributed, most of which were released in the waters of the Ocala National Forest. Plans were laid for a general rebuilding of this establishment in order to make it conform to the Bureau's standards of design and construction. It is proposed to increase the pond area and construct a laboratory and other facilities. These facilities are required for research work in aquiculture which is to be undertaken here.

Fry were transferred to rearing ponds at the Palestine, W. Va., station, which is operated in cooperation with the West Virginia Conservation Commission. It is estimated that a total of 150,000

fish were on hand June 30.

The Norris, Tenn., hatchery, which is operated in cooperation with the Tennessee Valley Authority, liberated its output of fish in Norris Lake.

At the Harrison Lake, Va., station two additional ponds and a spill-way to the reservoir were constructed. The output of fish was on a level with that of last year. However, efforts are being made to increase the production by planting aquatic plants in the ponds.

From the Tishomingo, Okla., station 635,500 fingerling fish were distributed. However, pond acreage at this point is not sufficient to produce enough fish to take care of all requests in that locality, and

plans are being made to develop a new series of ponds.

Cold weather prevailed at the Natchitoches, La., station during the bass spawning season with consequent curtailment of the output of this species. The production of other pond species was increased and the total production was in excess of that of last season. Experiments in the propagation of spoonbill catfish were continued. The breeders appeared to be acclimated and are occasionally seen taking food, but no spawning activities were noticed.

#### MISSISSIPPI RIVER TERRITORY

The La Crosse, Wis., station is the headquarters for various activities of the Division in the Mississippi Valley. Rescue operations in the Upper Mississippi Wildlife and Fish Refuge were continued from Marquette, Guttenberg, Bellevue, Homer, and Fairport. 43,194,485 fish was salvaged. The output of fish from the semicontrolled ponds in this area was quite successful. The total production from these ponds was 988,470 fish, of which number 975,795 were black bass—the species that is most in demand.

Approximately 1,000,000 large fingerling rainbow, brook, and Loch Leven trout were distributed from the La Crosse station. Several thousand of these trout were consigned to 26 Wisconsin and 11 Minnesota cooperative nurseries and Forest Service rearing stations. A carload of specimens was collected in this area for the Bureau's aquarium in Washington, D. C., and the aquarium in New York City.

Construction activities were continued at Genoa in cooperation with the W. P. A. In addition to the excavating of ponds, a one and one-half story, five-room residence and garage were built.

The Homer, Minn., station is being developed as a supply depot for stations in that territory and is also being equipped to render shop service in the maintenance of automotive and vessel equipment. This does not interfere with rescue operations which are of short duration only.

Production of pondfish at the Fairport, Iowa, station was on a level with that of last year. Further experiments in the culture of spoonbill catfish were undertaken at this point also, but the results were negative. In addition to the salvaging of fish from nearby waters, carp and buffalofish eggs were obtained from commercial fishermen, fer-

tilized, and planted upon the spawning grounds.

The Rochester, Ind., station established an all-time record in the production of pondfishes. This was due partly to the creation of additional pond space at this point as well as at the Argos auxiliary. The total output of all species from both sources was 1,001,760—an increase of 582,945 over the previous year. A large number of these fish were liberated in the waters from which the station had secured its brood stock. Daphnia culture for fish food was quite successful during the spring months. The office building was completed and all buildings were painted. At the close of the year additional ponds were being built and the creek riprapped, under the auspices of the

The production of bass at the Lake Mills, Wis., station was approximately double that of the previous year. Trout culture was normal, 200,000 fingerlings being distributed for the stocking of waters in that locality. Three large and seven small ponds were excavated and the surrounding grounds were landscaped. This construction work was

carried on with W. P. A. labor.

#### AQUARIUM

The displays of fresh-water food, game, forage, and predatory fish, maintained in the public aquarium of the Department of Commerce, have continued to be a magnet of public attraction. The number of specimens shown has ranged from 1,500 to 2,000. Included among these were a number of the showy tropical species which are so popular for home aquaria. As heretofore, demonstrations of model hatchery apparatus and methods were displayed, utilizing eggs of salmon, trout, whitefish, shad, and yellow perch in season.

A gradually increasing percentage of chlorine used in the District of Columbia water supply is threatening to limit the survival of the more delicate forms. Consideration is being given to the installation

of dechlorination equipment.

There was acquired a series of portable aquaria which could be utilized in handling small exhibits of live fishes which might be required for educational or conservation exhibits away from the main

As usual, the Bureau's hatcheries were drawn on freely as a source of aquarium specimens, and the distribution cars and trucks were utilized for transporting them. Consequently, the operating costs of this establishment were held at a low level in comparison with the normally heavy costs of operating such a public institution.

#### DISTRIBUTION OPERATIONS

A greater number of requests for consignments of fish were received this year from individuals and clubs than for several years previous, the total being 10,723. This does not include a number of blanket applications from the national forests, national parks, and other Government agencies, upon which hundreds of thousands of fish

were assigned.

The distribution cars engaged in the delivery of fish to applicants this year made 91 trips and carried an average of 260 pails per trip. In making this distribution the cars traveled 60,255 paid miles and 12,307 free miles. Detached messengers traveled 68,336 paid miles and 11,022 free miles in delivering fish to applicants. As heretofore, the Bureau was favored with free transportation and reduced rates by a number of railroads. The distributing of fish by trucks, within a comparatively short radius of our hatcheries, is becoming more prevalent each year. Truck deliveries during the year aggregated 245,000 miles, which was more than double that of last year. Bureau received the cooperation of several State conservation departments in distributing the fish produced at our hatcheries to applicants in their respective States.

Unfortunately, due to limited distribution funds, the practice of asking applicants in some localities to call at our hatcheries to receive their allotments of fish had to be continued. This, however, was not always practicable from the applicants' standpoint, and in such cases the uncalled-for fish were either assigned to State conservation depart-

ments or planted in public waters.

## Summary, by States, of the distribution of fish, fiscal year 1938

State and species	Number	State and species	Number
Alabama:		Iowa—Continued.	
Rainbow trout Largemouth black bass	31, 500 523, 815 3, 000	Carp	363, 200
